Question 1: The surface of water in a water tank on the top of a house is 4 m above the tap level. Find the pressure of water at the tap when the tap is closed, is it necessary to specify that the tap is closed? Take \( g = 10 \text{ m s}^{-2} \).

Solution:
Pressure \( P = \rho gh \)
Here \( \rho = 1000 \text{ kg/m}^3 \), \( g = 10 \text{ m s}^{-2} \) and \( h = 4 \text{ m} \)

\[ P = 40000 \text{ N/m}^2 \]

Yes, it necessary to state that the tap is closed. If tap is open the level of water will decrease and hence the pressure will decrease, the pressure at the tap is atmospheric.

Question 2: The heights of mercury surfaces in the two arms of the manometer shown in figure (below) are 2 cm and 8 cm. Atmospheric pressure = \( 101 \times 10 \text{ N m}^{-2} \). Find (a) the pressure of the gas in the cylinder and (b) the pressure of mercury at the bottom of the U tube.

Solution:
(a) Pressure at the bottom of the tubes should be same when considered for both limbs.

From figure,
\[ P_a + \rho_{Hg} h_1 g = P_g + \rho_{Hg} h_2 g \]

\[ \Rightarrow P_g = P_a + \rho_{Hg} g(h_1 - h_2) \]

(b) Pressure of mercury at the bottom of tube

\[ P = P_a + \rho_{Hg} h_1 g \]

**Question 3:** The area of cross section of the wider tube shown in figure (below) is 900 cm². If the boy standing on the piston weighs 45 kg, find the difference in the levels of water in the two tubes.

![Diagram of a tube with a boy standing on a piston](https://byjus.com)

**Solution:**

Pressure = Force/Area

\[ F = mg = 45 \times 9.8 = 441 \text{ N} \]

and \( A = 900 \text{ cm}^2 \) or \( 0.09 \text{ m}^2 \)

Therefore, Pressure = \( \frac{441}{0.09} = 4900 \text{ N} \) ...(1)

Also, pressure can be represented as, \( P = \rho g \Delta h \)
Where, \( \Delta h \) is the height difference and \( \rho \) = density

Density of water = \( \rho = 1000 \text{ kg/m}^3 \)
The pressure at the bottom of the container is due to the water and the atmospheric pressure. The force exerted on the bottom of the container is calculated using the pressure and the area.

(a) Pressure at bottom of the container = pressure due to water + atmospheric pressure.

\[ P = \rho g h + P_{atm} \]

\[ = (1000 \times 10 \times 0.2) + 1 \times 10^5 \]

\[ = 1.02 \times 10^5 \text{ N/m}^2 \]

Now, force exerted on the bottom of the container = \( F = P \times \text{Area} \)

\[ = (1.02 \times 10^5) \times 0.002 \]
\[ F = 204 \text{ N} \]

(b) Vertical forces (\(F'\)) includes the weight of the water and the force due to atmospheric pressure.

\[
F' = mg + [P_{\text{atm}} \times \text{area}]
\]

\[
= (0.5 \times 9.8) + (0.002 \times 1 \times 10^5)
\]

\[ F' = 205 \text{ N} \]

Therefore, total upward force = \(F' - F = 1 \text{ N} \)

**Question 5:** Suppose the glass of the previous problem is covered by a jar and the air inside the jar is completely pumped out. (a) What will be the answers to the problem? (b) Show that the answers do not change if a glass of different shape is used provided the height, the bottom area and the volume are unchanged.

**Solution:**
If the glass is covered by a jar and the air inside the jar is completely pumped out.

Pressure at the bottom of the glass = \(P = \rho gh = 1000 \times 10 \times 0.2 = 2000 \text{ N/m}^2\)

The downward force is \(F = P \times \text{area} = 2000 \times 0.002 = 4\text{N} \)

(b) Vertical force is equal to the weight of the water = \(mg = 0.5 \times 10 = 5\text{N} \)

The horizontal forces again cancel out. So the total upward force = \(1\text{N} \)

It glass of different shape is used provided the volume, height and area remain same, no change in answer will occur.

**Question 6:** If water be used to construct a barometer, what would be the height of water column at standard atmospheric pressure (76 cm of mercury)?

**Solution:**
Standard atmospheric pressure is always pressure exerted by 76 cm Hg column.

\[ P_{atm|Hg} = \rho_{Hg} gh = 13.6 \times 10^3 \times g \times 0.76 \quad (1) \]

For water, \( P_{atm|water} = \rho_{water} gh = 1000 \times g \times 0.76 \quad (2) \)

Atmospheric pressure: \( P_{atm|Hg} = P_{atm|water} \)

equating both the equations, we get

\[ h = 1033.6 \text{ cm}, \text{ is the required height of the water.} \]

**Question 7:** Find the force exerted by the water on a 2 m\(^2\) plane surface of a large stone placed at the bottom of a sea 500 m deep. Does the force depend on the orientation of the surface?

**Solution:**

Pressure = \( P = \rho gh = 1000 \times 10 \times 500 = 5 \times 10^6 \text{ N/m}^2 \)

and force = \( F = \text{Pressure} \times \text{Area} = (5 \times 10^6) \times 2 = 10^7 \text{ N} \)

**Question 8:** Water is filled in a rectangular tank of size 3 m × 2 m × 1 m. (a) Find the total force exerted by the water on the bottom surface of the tank. (b) Consider a vertical side of area 2 m × 1 m. Take a horizontal strip of width \( \delta x \) meter in this side, situated at a depth of \( x \) meter from the surface of water. Find the force by the water on this strip (c) Find the torque of the force calculated in part (b) about the bottom edge of this side. (d) Find the total force by the water on this side. (e) Find the total torque by the water on the side about the bottom edge. Neglect the atmospheric pressure and take \( g = 10 \text{ m s}^{-2} \).

**Solution:**

Dimensions of rectangular tank: 3 m × 2 m × 1 m.

(a) Pressure at the bottom of the tank = \( P = \rho gh \)

\[ = 1000 \times 10 \times 1 = 10^4 \text{ N/m}^2 \]
Area of the bottom of the tank = \( A = lb = 3 \times 2 = 6 \text{ m}^2 \)

Now, force = \( F = \text{Pressure} \times \text{Area} = 10^4 \times 6 = 60000 \text{ N} \)

(b) \( \rho gh = \rho gx \)

Area of strip = \( A = 2 \text{ dx} \)

So, the force on the strip = \( F = PA = \rho gx \times 2 \text{ dx} \)

= \( (20000 \times \text{dx}) \text{ N} \)

(c) Let us first find the perpendicular distance (d) of the strip from the bottom edge.

\( d = h - x = (1 - x) \text{ m} \)

Now, Torque = Force \times \text{perpendicular distance} = F \times d

= \( (20000 \times (1 - x) \text{dx}) \text{ N-m} \)

(d) Total force

\[ F = 20000 \int_0^1 x \text{dx} = 20000 \left[ \frac{x^2}{2} \right]_0^1 = 10000 \text{ N} \]

(e) Total Torque

\[ \tau = \int_0^1 20000x(1 - x) \text{dx} = \frac{10000}{3} \text{ N-m} \]

**Question 9:** An ornament weighing 36 g in air, weighs only 34 g in water. Assuming that some copper is mixed with gold to prepare the ornament, find the amount of copper in it. Specific gravity of gold is 19.3 and that of copper is 8.9.

**Solution:** The density of copper and gold are 8.9 and 19.3 respectively.

\[ V = \frac{x}{8.9} + \frac{(36-x)}{19.3} \quad \text{(1)} \]
When ornament placed in water, it displaces water equal to its weight. The density of water = $\rho_{\text{water}} = 1 \text{ g/cm}^3$

Weight of the water displaced = $w = mg = \nu \rho_{\text{water}} g = \nu g$ ....(2)

ornament weighs 34 g in water. (Given)

The buoyant force = $F_b = mg = (36-34) = 2g$ ...(3)

Buoyant force is equal to weight of the water displaced.

$\nu g = 2g$

$\Rightarrow [x/8.9 + (36-x)/19.3] \text{ g} = 2g$

or $x = 23.14/10.4 = 2.22 \text{ grams (approx)}$

The weight of copper in the ornament is 2.22 grams.

**Question 10:** Refer to the previous problem. Suppose, the goldsmith argues that he has not mixed copper or any other material with gold, rather some cavities might have been left inside the ornament. Calculate the volume of the cavities left that will allow the weights given in that problem.

**Solution:**
Total volume of the Ornament($y$) = Volume of gold + volume of cavity
Total volume ($y$) = $36/19.3 + \nu$

Using, Principle of Flotation,
The volume of the water displaced is also $y \text{ cm}^3$

The mass of the water displaced = $\nu$ grams
The weight of the water displaced = $\nu g$

$\nu g = 2g$
or \( y = 2 \)

Therefore, \( \frac{36}{19.3} + v = 2 \)

or \( v = 0.13 \text{ cm}^3 \)

Question 11: A metal piece of mass 160 g lies in equilibrium inside a glass of water (figure below). The piece touches the bottom of the glass at a small number of points. If the density of the metal is 8000 kg m\(^4\), find the normal force exerted by the bottom of the glass on the metal piece.

Solution:

Volume of metal immersed, \( V = \frac{m}{\rho} = \frac{0.16}{8000} = 0.00002 \text{ m}^3 \)

Weight of the water displaced = \( F_b = V \times \rho_{\text{water}} \times g \)

\[ = 0.00002 \times 1000 \times 10 \]

\[ = 0.2 \]

Find the normal force exerted by the bottom of the glass on the metal piece:

Vertical forces consist of the normal reaction (\( N \)) from the surface (upwards), the weight of the metal (downwards) and the buoyant force (upwards) to maintain the balance of vertical forces.

\[ N + F_b = mg \]

\[ \Rightarrow N = (0.16\times10) - 0.2 = 1.4 \text{ N} \]

The normal reaction is \( 1/4 N \) in total.
**Question 12:** A ferry boat has internal volume $1 \text{ m}^3$ and weight $50 \text{ kg}$. (a) Neglecting the thickness of the wood, find the fraction of the volume of the boat immersed in water. (b) If a leak develops in the bottom and water starts coming in, what fraction of the boat’s volume will be filled with water before water starts coming in from the sides?

**Solution:**

(a) Buoyant force should be equal to the weight of the boat.

$$v \rho \text{w} g = mg$$

$$v \times 1000 = 50$$

or $v = 1/20 \text{ m}^3$

(b) Let $V_b$ be the volume of boat filled with water before water starts coming in from the sides. here $V_b = 1 \text{ m}^3$

Therefore, buoyant force $= F_b = V_b \rho \text{w} g = 1000 \text{ gN}$

The volume of water $= V_w = m_w/\rho \text{w} = 950/1000 = 0.95 \text{ m}^3$

[Here $m_w + 50 = 1000$ or $m_w = 950 \text{ kg}$]

Now, fraction of water filled in the boat $= 0.95 = 19/20$

**Question 13:** A cubical block of ice floating in water has to support a metal piece weighing $0.5 \text{ kg}$. What can be the minimum edge of the block so that it does not sink in water? Specific gravity of ice $0.9$.

**Solution:**

Let the edge of the cube be “$x \text{ cm}$”.

Volume of the cube $= V = x^3/10^6 \text{ m}^3 ...(1)$

And buoyant force $= F_b = m_{\text{mg}} + V \rho_i g = 0.5 + 900 v ...(2)$
Also, buoyant force is equal to the weight of the water displaced

\[ V \times 1000 \text{ g} = 0.5 + 900 \]

\[ 100V = 0.5 \]

Using (1),

\[ \frac{x^3}{10^6} = \frac{0.5}{100} \]

or \( x = 17 \text{ cm} \) (approx)

**Question 14:** A cube of ice floats partly in water and partly in K.oil (figure below). Find the ratio of the volume of ice immersed in water to that in K.oil. Specific gravity of K.oil is 0.8 and that of ice is 0.9.

![Diagram of cube floating in water and K.oil]

**Solution:**

Density of water = \( \rho_w = 1000 \text{ kg/m}^3 \)

Density of ice = \( \rho_i = 0.9 \times 1000 = 900 \text{ kg/m}^3 \)

Density of K.oil = \( \rho_o = 1000 \text{ kg/m}^3 \)

The weight of the cube of ice = \( w_i = \text{volume} \times \text{density} \times g = (a+b)900\text{g} \) ...(1)

Where \( a = \text{volume of cube immersed in water} \) and \( b = \text{volume immersed in K.oil} \)

The total buoyant force = sum of forces exerted by the liquids.

\[ F_b = a \rho_w + b \rho_o = a(1000) + b(800) \) ....(2)
From (1) and (2)

\[ a(1000) + b(800) = (a+b)900 \]

\[ \Rightarrow a/b = 1 \]

The ratio of the volumes immersed is 1:1.

**Question 15:** A cubical box is to be constructed with iron sheets 1 mm in thickness. What can be the minimum value of the external edge so that the cube does not sink in Water? Density of iron = 8000 kg m\(^{-3}\) and density of water = 1000 kg m\(^{-3}\).

**Solution:**
Density of iron = \( \rho_i = 8000 \text{ kg/m}^3 \) and density of water = 1000 kg m\(^{-3}\).
Let “x cm” be the edge of the iron sheet.

Surface area = \( 6x^2 \text{ cm}^2 \)

Volume of the iron sheets = \( v = 6x^2 \times 0.1 = (0.6/10^6) \text{ m}^3 \)

Therefore, mass of the iron box = \( m_b = \rho_i \times v = 4.8 \times 10^{-3} \times x^2 \text{ kg} \) ...(1)

Volume of the cube = \( V' = x^3 \text{ cm}^3 = (x^3/10^6) \text{ m}^3 \)

Buoyant force = \( F_b = V' \rho_w g \)

\[ = (x^3/10^6) \times 1000 \times g \]

\[ = (x^3/10^3) \text{ gN} \text{ }.....(2) \]

Here, buoyant force is equal to the weight of the box.

From (1) and (2)

\[ 4.8 \times 10^{-3} \times x^2 = (x^3/10^3)g \]

\[ \Rightarrow x = 4.8 \text{ cm} \]
Question 16: A cubical block of wood weighing 200 g has a lead piece fastened underneath. Find the mass of the lead piece which will just allow the block to float in water. Specific gravity of wood is 0’S and that of lead is 11.3.

Solution:

Total mass of the system = mass of wood \( m_w \) + mass of lead \( m_{Pb} \)

\[ = 200 + m_{Pb} \]  

...(1)

Density of wood = \( \rho_w = 0.8 \text{ g/cm}^3 \)

Volume of the wooden block = \( v_w = \frac{m_w}{\rho_w} = 250 \text{ cm}^3 \)

Density of lead = \( \rho_{Pb} = 11.3 \text{ g/cm}^3 \)

Volume of lead piece = \( v_{Pb} = \frac{m_{Pb}}{\rho_{Pb}} = \frac{m_{Pb}}{11.3} \text{ cm}^3 \)

Therefore, the volume of water displaced would be equal to the total volume.

\[ V = v_w + v_{Pb} = 250 + \frac{m_{Pb}}{11.3} \text{ cm}^3 \]

Buoyant force = \( F_b = V \rho_w g = (250 + m_{Pb}/11.3) \times 1 \times g \) ....(2)

Now, (1) = (2), we get

\[ 200 + m_{Pb} = (250 + m_{Pb}/11.3) \times 1 \times g \]

\[ => m_{Pb} = 54.8 \text{ g} \]

Question 17: Solve the previous problem if the lead piece is fastened on the top surface of the block and the block is to float with its upper surface just dipping into water.

Solution:

Volume immersed is only due to the wooden block.

The buoyant force = \( F_b = 250 \text{ g} \)
Now, Total mass = \( F_b \)

\[ \Rightarrow 200 + m_{Pb} = 250 \text{ g} \]

or \( m_{Pb} = 50 \text{ g} \)

The mass of the lead piece is 50 g.

**Question 18:** A cubical metal block of edge 12 cm floats in mercury with one fifth of the height inside the mercury. Water is poured till the surface of the block is just immersed in it. Find the height of the water column to be poured. Specific gravity of mercury = 13.6.

**Solution:**

Volume immersed in mercury = \( v_m = \left(\frac{12^3}{5}\right) \text{ cm}^3 \)

Buoyant force on the block is equal to the weight of the mercury displaced = \( \rho_m \times v_m \)

\[ = 13.6 \times \left(\frac{12^3}{5}\right) \text{ g} \] ....(1)

Volume of block in water = \( v_w = 12^3 \times h \text{ cm}^3 \)

Volume of block in mercury = \( v'_m = 12^2(12-h) \text{ cm}^3 \)

Now, buoyant force = \( F_b = \left[ v_m \rho_w + v'_m \rho_m \right] \text{g} \)

\[ = 12^2 h + 12^2 (12-h)13.6 \text{ g} \] ....(2)

The buoyant force is equal to the weight of the cube.

(1) = (2)

\[ \Rightarrow 13.6 \times \left(\frac{12^3}{5}\right) \text{ g} = 12^2 h + 12^2 (12-h)13.6 \text{ g} \]

Solving above equation, we have
h = 10.4 cm

Therefore, water needs to be poured to a height of 10.4 cm.

Question 19: A hollow spherical body of inner and outer radii 6 cm and 8 cm respectively floats half-submerged in water. Find the density of the material of the sphere.

Solution:

A hollow spherical body of inner and outer radii 6 cm and 8 cm respectively floats half-submerged in water.

Find density of the material of the sphere:

Here, Mass of the water displaced = Mass of the material,

\[ \rho_w \times V_i = V_b \times \rho \]

\[ \Rightarrow 1000 \times \left(\frac{2}{3}\right) \pi \times 8^3 = \left(\frac{4}{3}\right)\pi \times (8^3 - 6^3)\rho \]

Solving above equation, we have

\[ \rho = 865 \text{ kg/m}^3 \]

Question 20: A solid sphere of radius 5 cm floats in water. If a maximum load of 0.1 kg can be put on it without wetting the load, find the specific gravity of the material of the sphere.

Solution:

A solid sphere of radius 5 cm floats in water. If a maximum load of 0.1 kg can be put on it without wetting the load

Volume of sphere = \[ v = \frac{4\pi r^3}{3} = \frac{(5\pi)}{3} \times 10^{-4} \text{ m}^3 \]

Weight of water displaced = \[ \rho_w \times v_g = \frac{(5\pi)}{3} \text{ N} \]

Now, Weight of sphere + Load = weight of displaced water
\[ \rho_s \, v_g + 0.1 \times 10 = \rho_w \, v_g \]

or \[ \rho_s = \frac{\rho_w \, v_g - 1}{v_g} \]

Therefore, specific gravity = \[ \frac{\rho_s}{\rho_w} = 1 - \frac{1}{[5\pi/3]} = 0.81 \]

Which is the specific gravity of sphere.

**Question 21:** Find the ratio of the weights, as measured by a spring balance, of a 1 kg block of iron and a 1 kg block of wood. Density of iron = 7800 kg m\(^{-3}\), density of wood = 800 kg m\(^{-3}\) and density of air = 1293 kg m\(^{-3}\).

**Solution:**
The weight of iron block = \(w_i = m_i \, g - v_i \, \rho_a \, g = m_i [1 - (1/\rho_i) \, \rho_a]g\)

and weight of wooden block = \(w_w = m_w \, g - v_w \, \rho_a \, g = m_w [1 - (1/\rho_w) \, \rho_a]g\)

Now, ratio of \(w_i\) and \(w_w\):

\[ \frac{w_i}{w_w} = \frac{m_i [1 - \frac{1}{\rho_i} \, \rho_a]g}{m_w [1 - \frac{1}{\rho_w} \, \rho_a]g} \]

\[ \Rightarrow \frac{w_i}{w_w} = \frac{1 - \frac{1293}{7800}}{1 - \frac{1293}{800}} = 1.0015 \]

**Question 22:** A cylindrical object of outer diameter 20 cm and mass 2 kg floats in water with its axis vertical. If it is slightly depressed and then released, find the time period of the resulting simple harmonic motion of the object.

**Solution:**
Buoyant force = \(F_b = v \, \rho_w \, g = (\pi \, r^2 \, x) \rho_w \, g\)

Where \(v = \) volume of the immersed object
and ma = (π r^2 x)ρ_w g

or a = (π r^2 x ρ_w g)/2000

Now, time period = T = 2π √(displacement/acceleration)

=> T = 0.5 sec (approx)

**Question 23:** A cylindrical object of outer diameter 10 cm, height 20 cm and density 8000 kg m^{-3} is supported by a vertical spring and is half dipped in water as shown in figure(below). (a) Find the elongation of the spring in equilibrium condition. (b) If the object is slightly depressed and released, find the time period of resulting oscillations of the object. The spring constant =500 N m^{-1}.

**Solution:**

(a) In the equilibrium condition, the weight of the cylinder, is supported by the spring and the buoyant force.

kx + ρ_w g = mg

where v is volume = πr^2(h/2)

=> 500x + (π(0.05)^2 x0.1x10x1000) = π((0.05)^2 x 0.2x8000x10)

Solving above equation, we get

x = 23.5 cm

(b) Driving force = F = kx + ρ_w g
Question 24: A wooden block of mass 0.5 kg and density 800 kg m$^{-3}$ is fastened to the free end of a vertical spring of spring constant 50 N m$^{-1}$ fixed at the bottom. If the entire system is completely immersed in water find (a) the elongation (for compression) of the spring in equilibrium and (b) the time-period of vertical oscillations of the block when it is slightly depressed and released.

Solution:

(a) The weight of the block is balanced by the spring and the buoyant force.

\[ mg = kx + \rho_w g \]

\[ 0.5 \times 10 = 50x + (0.5/800) \times 1000 \times 10 \]

Solving for \( x \),

\[ x = 2.5 \text{ cm} \]

(b) \( a = kx/m \)

\( w^2x = kx/m \)

Time period \( T = 2\pi \sqrt{m/k} = (\pi/5) \text{ sec} \)

Question 25: A cube of ice of edge 4 cm is placed in an empty cylindrical glass of inner diameter 6 cm. Assume that the ice melts uniformly from each side so that it always retains its cubical shape. Remembering that ice is lighter than water, find the length of
the edge of the ice cube at the instant it just leaves contact with the bottom of the glass.

**Solution:**
The weight of the remaining ice will be balanced by the buoyant force provided from the melted water.

\[ mg = \rho_w g \]

The mass of the ice = \( m = x^3 \rho_i \)

\[ \Rightarrow x^3 \times 0.9 = x^2 \times h \times 1 \]

\[ \Rightarrow \quad h = 0.9 \times x \]

Volume of water formed = \( 4^3 - x^3 = \pi r^2 h - x^2 h \)

\[ x = 2.26 \text{ cm} \]

**Question 26:** A U-tube containing a liquid is accelerated horizontally with a constant acceleration \( \alpha_o \). If the separation between the vertical limbs is \( l \), find the difference in the heights of the liquid in the two arms.

**Solution:**
Balance all the vertical forces on the tube.

\[ P_a A + \alpha_o = P_a + Ahg \]

Where \( P_a \) is atmospheric pressure.

\[ \Rightarrow \alpha_o l = hg \]

or \( h = \frac{\alpha_o}{g} \)

**Question 27:** At Deprayag (Garhwal, UP) river Alaknanda mixes with the river Bhagirathi and becomes river Ganga. Suppose Alaknanda has a width of 12 m, Bhagirathi has a width of 8 m and Ganga has a width of 16 m. Assume that the depth of water is same in the three rivers. Let the average speed of water in Alaknanda be 20 km
h⁻¹ and in Bhagirathi be 16 km h⁻¹. Find the average speed of water in the river Ganga.

Solution:
The sum of the volume flow from Alaknanda and Bhagirathi is equal to the volume flow in Ganga.
Let the depth of the rivers be "d"

\[ v_A \times 12 \times d + v_B \times 8 \times d = v_G \times 16 \times d \]

=> \( v_G = \frac{23}{6} \) km/h

Question 28: Water flows through a horizontal tube of variable cross section (figure below). The area of cross section at A and B are 4 mm² and 2 mm² respectively. If 1 cc of water enters per second through A, find (a) the speed of water at A, (b) the speed of water at B and (c) the pressure difference \( P_A - P_B \).

Solution:
(a) The total volume is equal to area times velocity.
\[ v_A \times a_v = v \]

Where \( v_A \) is the velocity in tube.

=> \( 4 \times 10^{-2} \times v_A = 1 \)

=> \( V_A = 25 \) cm/s

(b) Let the velocity in tube B, \( v_B \)

For steady flow: \( v_A \times a_A = v_B \times a_B \)

=> \( 25 \times 4 \times 10^{-2} = v_B \times 2 \times 10^{-2} \)
=> \( V_B = 50 \text{ cm/s} \)

(c) From Bernoulli equation,

\[
P_A + \frac{1}{2} \rho v_A^2 = P_B + \frac{1}{2} \rho v_B^2
\]

=> \( P_A - P_B = \frac{1}{2} \rho [v_B^2 - v_A^2] \)

= \( \frac{1}{2} \times 1000 \times (0.5^2 - 0.25^2) \)

= \( 94 \text{ N/m}^2 \)

**Question 29:** Suppose the tube in the previous problem is kept vertical with A upward but the other conditions remain the same. The Separation between the cross sections at A and B is 15/16 cm. Repeat parts (a), (b) and (c) of the previous problem. Take \( g = 10 \text{ m/s}^2 \).

**Solution:**

\( V_A = 25 \text{ cm/s and } V_B = 50 \text{ cm/s} \) [from previous problem solution]

As changing the orientation doesn’t change the volume of water flowing from the tubes.

(c) From Bernoulli’s equation

\[
P_A + \frac{1}{2} \rho v_A^2 + \rho gh_A = P_B + \frac{1}{2} \rho v_B^2 + \rho gh_B
\]

\( \Rightarrow P_A - P_B = \frac{1}{2} \times 1000 \times [0.5^2 - 0.25^2] - 1000 \times 10 \times \frac{15}{16 \times 10^2} \)

= \( 0 \)

Therefore, pressure difference is \( 0 \text{ N/m}^2 \)

**Question 30:** Suppose the tube in the previous problem is kept vertical with B upward. Water enters through B at the rate of \( 1 \text{ cm}^3 \text{s}^{-1} \). Repeat parts (a), (b) and (c). Note that the speed decreases as the water falls down.
Solution:

(a) The total volume is equal to area times velocity.

\[ V = a_B \times v_B \]

Where, \( v = 1 \text{ cm}^3 \), \( a_A = \text{area of cross-section of tube A} = 4 \text{ mm}^2 \) and \( a_B = \text{area of cross-section of tube B} = 2 \text{ mm}^2 \)

\[ => v_B = 50 \text{ cm/s} \]

(b) Let \( v_b \) be the velocity in tube

\[ v_A \times a_A = v_B \times a_B \]

\[ => v_A = 25 \text{ cm/s} \]

(c) From Bernoulli equation

\[ P_A + \frac{1}{2} \rho v_A^2 + \rho gh_A = P_B + \frac{1}{2} \rho v_B^2 + \rho gh_B \]

\[ \Rightarrow P_A - P_B = \frac{1}{2} \times 1000 \times [0.5^2 - 0.25^2] + 1000 \times 10 \times \frac{15}{16 \times 10^2} \]

\[ = 187.5 \text{ N/m}^2 \]

\[ \Rightarrow P_A - P_B = 188 \text{ N/m}^2 \text{ (approx)} \]

Question 31: Water flows through a tube shown in figure (below). The areas of cross section at A and B are 1 cm² and 0.5 cm² respectively. The height difference between A and B is 5 Cm. If the speed of water at A is 10 cm s⁻¹, find (a) the speed at B and (b) the difference in pressures at A and B.
Solution:
(a) From equation of continuity,

\[ v_A \times a_A = v_B \times a_B \]

\[ 0.1 \times 1 = 0.5 \times v_B \]

\[ => v_B = 20 \text{cm/s} \]

(b) From Bernoulli's equation

\[ P_A + \frac{1}{2} \rho v^2_A + \rho g h_A = P_B + \frac{1}{2} \rho v^2_B + \rho g h_B \]

\[ => P_B - P_A = \rho g [h_B - h_A] - \frac{1}{2} \rho [v^2_B - v^2_A] \]

\[ = 1000 \times 10 \times 0.05 - \frac{1}{2} \times 1000 \times [0.2^2 - 0.1^2] \]

\[ = 485 \text{N/m}^2 \]

**Question 32:** Water flows through a horizontal tube as shown in figure (below). If the difference of heights of water column in the vertical tubes is 2 cm, and the areas of cross section at A and B are 4 cm\(^2\) and 2 cm\(^2\) respectively, find the rate of flow of water across any section.

![Diagram](https://byjus.com)

**Solution:**

Equation of continuity: \[ v_A \times a_A = v_B \times a_B \]

\[ => v_B = 2 \times v_A \]

Where \(v_A\) and \(v_B\) speed of water at A and speed of water at B respectively.
a_A = Area of cross-section of tube A and a_B = Area of cross-section of tube B

Also, given \( h = \) difference in height in the two columns = 2 cm

Pressure difference between A and B: \( P_A - P_B = \rho gh = 1000 \times 10 \times 0.02 = 200 \text{ N/m}^2 \)

By Bernoulli’s equation,

\[
P_A + \frac{1}{2}\rho [v_B^2 - v_A^2] = 200 = \frac{1}{2} \times 1000 \times [4v_A^2 - v_A^2]
\]

or \( v_A^2 = \frac{400}{3 \times 100} \)

or \( v_A = 36.51 \text{ cm/s} \)

Rate of flow = \( v_A \times a_A = 36.51 \times 4 = 146 \text{ cm}^3/\text{s} \) (approx)

**Question 33:** Water flows through the tube shown in figure (below). The areas of cross section of the wide and the narrow portions of the tube are 5 cm\(^2\) and 2 cm\(^2\) respectively. The rate of flow of water through the tube is 500 cm\(^3\) s\(^{-1}\). Find the difference of mercury levels in the U-tube.

![Diagram of U-tube](https://byjus.com)

**Solution:**

Equation of continuity: \( v_A \times a_A = v_B \times a_B \)

Where \( v_A \) and \( v_B \) are velocities of flow at A and B

\( v_A \times 5 = 500 \)
=> \( v_A = 100 \text{ cm/s or } 1 \text{ m/s} \)

Similarly, \( v_B = 250 \text{ cm/s or } 2.5 \text{ m/s} \)

Now, the pressure difference between the points,

\[ P_A - P_B = \rho_{Hg} gh = 13.6 \times 10 \times h \]

From the Bernoulli’s equation:

\[ P_A + \frac{1}{2} \rho v_A^2 = P_B + \frac{1}{2} \rho v_B^2 \]

\[ P_A - P_B = \rho_{Hg} gh = \frac{1}{2} \rho w (v_B^2 - v_A^2) \]

\[ 13.6 \times 980 \times h = \frac{1}{2} \times 1 \times [250^2 - 100^2] \]

\[ h = \frac{26250}{13.6 \times 980} = 1.969 \text{ cm} \]

**Question 34:** Water leaks out from an open tank through a hole of area 2 mm\(^2\) in the bottom. Suppose water is filled up to a height of 80 cm and the area of cross section of the tank is 0.4 m\(^2\). The pressure at the open surface and at the hole are equal to the atmospheric pressure. Neglect the small velocity of the water near the open surface in the tank. (a) Find the initial speed of water coming out of the hole. (b) Find the speed of water coming out when half of water has leaked out. (c) Find the volume of water leaked out during a time interval \( dt \) after the height remained is \( h \). Thus, find the decrease in height \( dh \) in terms of \( h \) and \( dt \). (d) From the result of part (e) find the time required for half of the water to leak out.

**Solution:**

(a) The velocity of water exiting at "a"

\[ v_A = \sqrt{2gh} \]

\[ => v_A = \sqrt{2 \times 10 \times 9.8} = 4 \text{ m/s} \]
(b) \( v_8 = \sqrt{(2g \cdot h/2)} = \sqrt{(2 \times 10 \times 0.4)} = \sqrt{8} \text{ m/s} \)

(c) Volume flow = \( V = \text{Area} \times \text{height} = Ah \)

Therefore, \( \frac{dv}{dt} = A \frac{dh}{dt} \) ...(1)

We know, \( V = av \text{ d}t \)

or \( V = a \sqrt{2gh} \text{ t} \)

Differentiating above equation, we have

\( \frac{dV}{dt} = A \sqrt{2gh} \) ...(2)

From (1) and (2)

\( a \sqrt{2gh} = A \frac{dh}{dt} \)

\( => 2 \times 10^{-6} (\sqrt{2gh}) = 0.4 \text{ dh/dt} \)

\( => \frac{dh}{\sqrt{2gh}} = 5 \times 10^{6} \text{ dt} \)

(d) Integrating above equation, we have

\( 5 \times 10^{-6} \int_{0}^{t} dt = \frac{1}{\sqrt{28}} \int_{0.4}^{h} \frac{dh}{\sqrt{h}} \)

\( \Rightarrow t = \frac{1}{\sqrt{20}} \times 2 \times [(0.4)^{1/2} - (0.8)^{1/2}] \times \frac{1}{5 \times 10^{-6}} \)

Solving for \( t \),

\( t = 6.51 \text{ h} \)

**Question 35:** Water level is maintained in a cylindrical vessel up to a fixed height \( H \). The vessel is kept on a horizontal plane. At what height above the bottom should a hole be made in the vessel so that the water stream coming out of the hole strikes the
horizontal plane at the greatest distance from the vessel (figure below)?

Solution 35: Water level is maintained in a cylindrical vessel up to a fixed height $H$.

Height of water above the hole = $H-h$

Velocity with which water = $v = \sqrt{2gh}$ and time of flight be $t$

$t = v(2h/g)$

The horizontal distance travelled = $x = vt = \sqrt{2g(H-h)} \times \sqrt{2h/g}$

$=> x = \sqrt{4Hh-h^2}$

To maximize this function: $dx/dh = 0$

$d/dh \sqrt{4Hh-h^2} = 0$

$h = H/2$
