Exercise 9.1   Page No: 9.5

1. Write the first terms of each of the following sequences whose n^{th} term are:
(i) $a_n = 3n + 2$
(ii) $a_n = (n – 2)/3$
(iii) $a_n = 3^n$
(iv) $a_n = (3n – 2)/5$
(v) $a_n = (-1)^n . 2^n$
(vi) $a_n = n(n – 2)/2$
(vii) $a_n = n^2 - n + 1$
(viii) $a_n = n^2 - n + 1$
(ix) $a_n = (2n – 3)/6$

Solutions:
(i) $a_n = 3n + 2$
            Given sequence whose $a_n = 3n + 2$
            To get the first five terms of given sequence, put n = 1, 2, 3, 4, 5 and we get
            $a_1 = (3 \times 1) + 2 = 3 + 2 = 5$
            $a_2 = (3 \times 2) + 2 = 6 + 2 = 8$
            $a_3 = (3 \times 3) + 2 = 9 + 2 = 11$
            $a_4 = (3 \times 4) + 2 = 12 + 2 = 14$
            $a_5 = (3 \times 5) + 2 = 15 + 2 = 17$
            ∴ the required first five terms of the sequence whose n^{th} term, $a_n = 3n + 2$ are 5, 8, 11, 14, 17.

(ii) $a_n = (n – 2)/3$

            Given sequence whose $a_n = \dfrac{n-2}{3}$
            On putting n = 1, 2, 3, 4, 5 then can get the first five terms

$$a_1 = \frac{1-2}{3} = \frac{-1}{3}; a_2 = \frac{2-2}{3} = 0$$

$$a_3 = \frac{3-2}{3} = \frac{1}{3}; a_4 = \frac{4-2}{3} = \frac{2}{3}$$

$$a_5 = \frac{5-2}{3} = 1$$

            ∴ the required first five terms of the sequence whose n^{th} term, $a_n = \dfrac{n-2}{3}$ are $\dfrac{-1}{3}, 0, \dfrac{1}{3}, \dfrac{2}{3}, 1.$

(iii) $a_n = 3^n$
            Given sequence whose $a_n = 3^n$
            To get the first five terms of given sequence, put n = 1, 2, 3, 4, 5 in the above
            $a_1 = 3^1 = 3;$
            $a_2 = 3^2 = 9;$
            $a_3 = 27;$
            $a_4 = 3^4 = 81;$

$a_5 = 3^5 = 243$.

∴ the required first five terms of the sequence whose n^{th} term, $a_n = 3^n$ are 3, 9, 27, 81, 243.

(iv) $a_n = (3n - 2)/ 5$

Given sequence whose $a_n = \dfrac{3n - 2}{5}$

To get the first five terms of the sequence, put n = 1, 2, 3, 4, 5 in the above
And, we get

$a_1 = \dfrac{3 \times 1 - 2}{5} = \dfrac{3 - 2}{5} = \dfrac{1}{5}$

$a_2 = \dfrac{3 \times 2 - 2}{5} = \dfrac{6 - 2}{5} = \dfrac{4}{5}$

$a_3 = \dfrac{3 \times 3 - 2}{5} = \dfrac{9 - 2}{5} = \dfrac{7}{5}$

$a_4 = \dfrac{3 \times 4 - 2}{5} = \dfrac{12 - 2}{5} = \dfrac{10}{5}$

$a_5 = \dfrac{3 \times 5 - 2}{5} = \dfrac{15 - 2}{5} = \dfrac{13}{5}$

∴ the required first five terms of the sequence are 1/5, 4/5, 7/5, 10/5, 13/5

(v) $a_n = (-1)^n 2^n$
Given sequence whose $a_n = (-1)^n 2^n$
To get first five terms of the sequence, put n = 1, 2, 3, 4, 5 in the above.
$a_1 = (-1)^1 . 2^1 = (-1).2 = -2$
$a_2 = (-1)^2 . 2^2 = (-1).4 = 4$
$a_3 = (-1)^3 . 2^3 = (-1).8 = -8$
$a_4 = (-1)^4 . 2^4 = (-1).16 = 16$
$a_5 = (-1)^5 . 2^5 = (-1).32 = -32$
∴ the first five terms of the sequence are – 2, 4, - 8, 16, - 32.

(vi) $a_n = n(n – 2)/2$

                    $a_n = \dfrac{n(n - 2)}{2}$

The given sequence is,
To get the first five terms of the sequence, put n = 1, 2, 3, 4, 5.
And, we get

$$a_1 = \frac{1(1-2)}{2} = \frac{1-1}{2} = \frac{-1}{2}$$

$$a_2 = \frac{2(2-2)}{2} = \frac{2.0}{2} = 0$$

$$a_3 = \frac{3(3-2)}{2} = \frac{3.1}{2} = \frac{3}{2}$$

$$a_4 = \frac{4(4-2)}{2} = \frac{4.2}{2} = 4$$

$$a_5 = \frac{5(5-2)}{2} = \frac{5.3}{2} = \frac{15}{2}$$

∴ the required first five terms are -1/2, 0, 3/2, 4, 15/2

(vii) $a_n = n^2 - n + 1$
The given sequence whose, $a_n = n^2 - n + 1$
To get the first five terms of given sequence, put n = 1, 2, 3, 4, 5.
And, we get
$a_1 = 1^2 - 1 + 1 = 1$
$a_2 = 2^2 - 2 + 1 = 3$
$a_3 = 3^2 - 3 + 1 = 7$
$a_4 = 4^2 - 4 + 1 = 13$
$a_5 = 5^2 - 5 + 1 = 21$
∴ the required first five terms of the sequence are 1, 3, 7, 13, 21.

(viii) $a_n = 2n^2 - 3n + 1$
The given sequence whose $a_n = 2n^2 - 3n + 1$
To get the first five terms of the sequence, put n = 1, 2, 3, 4, 5.
And, we get
$a_1 = 2.1^2 - 3.1 + 1 = 2 - 3 + 1 = 0$
$a_2 = 2.2^2 - 3.2 + 1 = 8 - 6 + 1 = 3$
$a_3 = 2.3^2 - 3.3 + 1 = 18 - 9 + 1 = 10$
$a_4 = 2.4^2 - 3.4 + 1 = 32 - 12 + 1 = 21$
$a_5 = 2.5^2 - 3.5 + 1 = 50 - 15 + 1 = 36$
∴ the required first five terms of the sequence are 0, 3, 10, 21, 36.

(ix) $a_n = (2n - 3)/ 6$

Given sequence whose, $a_n = \dfrac{2n - 3}{6}$
To get the first five terms of the sequence we put n = 1, 2, 3, 4, 5.
And, we get

$$a_1 = \frac{2.1 - 3}{6} = \frac{2 - 3}{6} = \frac{-1}{6}$$

$$a_2 = \frac{2.2 - 3}{6} = \frac{4 - 3}{6} = \frac{1}{6}$$

$$a_3 = \frac{2.3 - 3}{6} = \frac{6 - 3}{6} = \frac{3}{6} = 1/2$$

$$a_4 = \frac{2.4 - 3}{6} = \frac{8 - 3}{6} = \frac{5}{6}$$

$$a_5 = \frac{2.5 - 3}{6} = \frac{10 - 3}{6} = \frac{7}{6}$$

∴ the required first five terms of the sequence are -1/6, 1/6, 1/2, 5/6 and 7/6

Exercise 9.2   Page No: 9.8

1. Show that the sequence defined by $a_n = 5n - 7$ is an A.P., find its common difference.
Solution:

Given, $a_n = 5n - 7$
Now putting n = 1, 2, 3, 4 we get,
$a_1 = 5(1) - 7 = 5 - 7 = -2$
$a_2 = 5(2) - 7 = 10 - 7 = 3$
$a_3 = 5(3) - 7 = 15 - 7 = 8$
$a_4 = 5(4) - 7 = 20 - 7 = 13$
We can see that,
$a_2 - a_1 = 3 - (-2) = 5$
$a_3 - a_2 = 8 - (3) = 5$
$a_4 - a_3 = 13 - (8) = 5$
Since the difference between the terms is common, we can conclude that the given sequence
defined by $a_n = 5n - 7$ is an A.P with common difference 5.

2. Show that the sequence defined by $a_n = 3n^2 - 5$ is not an A.P.
Solution:

Given, $a_n = 3n^2 - 5$
Now putting n = 1, 2, 3, 4 we get,
$a_1 = 3(1)^2 - 5 = 3 - 5 = -2$
$a_2 = 3(2)^2 - 5 = 12 - 5 = 7$
$a_3 = 3(3)^2 - 5 = 27 - 5 = 22$
$a_4 = 3(4)^2 - 5 = 48 - 5 = 43$
We can see that,
$a_2 - a_1 = 7 - (-2) = 9$
$a_3 - a_2 = 22 - 7 = 15$
$a_4 - a_3 = 43 - 22 = 21$
Since the difference between the terms is not common and varying, we can conclude that the
given sequence defined by $a_n = 3n^2 - 5$ is not an A.P.

**3. The general term of a sequence is given by $a_n = -4n + 15$. Is the sequence an A.P.? If so, find its
15th term and the common difference.**
Solution:

Given, $a_n = -4n + 15$
Now putting n = 1, 2, 3, 4 we get,
$a_1 = -4(1) + 15 = -4 + 15 = 11$
$a_2 = -4(2) + 15 = -8 + 15 = 7$
$a_3 = -4(3) + 15 = -12 + 15 = 3$
$a_4 = -4(4) + 15 = -16 + 15 = -1$
We can see that,

$a_2 - a_1 = 7 - (11) = -4$
$a_3 - a_2 = 3 - 7 = -4$
$a_4 - a_3 = -1 - 3 = -4$
Since the difference between the terms is common, we can conclude that the given sequence defined by $a_n = -4n + 15$ is an A.P with common difference of -4.

Hence, the 15th term will be
$a_{15} = -4(15) + 15 = -60 + 15 = -45$

Exercise 9.3   Page No: 9.11

1. For the following arithmetic progressions write the first term a and the common difference d:
(i) - 5, -1, 3, 7,…
(ii) 1/5, 3/5, 5/5, 7/5,…
(iii) 0.3, 0.55, 0.80, 1.05,…
(iv) -1.1, – 3.1, – 5.1, – 7.1,…
Solution:

We know that if a is the first term and d is the common difference, the arithmetic progression is a, a + d, a + 2d + a + 3d,….

(i)   – 5, –1, 3, 7,…
        Given arithmetic series is – 5, –1, 3, 7,...
        c a, a + d, a + 2d + a + 3d,….
        Thus, by comparing these two we get, a = – 5, a + d = 1, a + 2d = 3, a + 3d = 7
        First term (a) = – 5
        By subtracting second and first term, we get
        (a + d) - (a) = d
        -1 - (- 5) = d
        4 = d
        ⇒ Common difference (d) = 4.

(ii)   1/5, 3/5, 5/5, 7/5, ...
        Given arithmetic series is 1/5, 3/5, 5/5, 7/5, ...
        It is seen that, it's of the form of 1/5, 2/5, 5/5, 7/5, ... a, a + d, a + 2d, a + 3d,
        Thus, by comparing these two, we get
        a = 1/5, a + d = 3/5, a + 2d = 5/5, a + 3d = 7/5
        First term (a) = 1/5
        By subtracting first term from second term, we get
        d = (a + d)-(a)
        d = 3/5 - 1/5
        d = 2/5
        ⇒ common difference (d) = 2/5

(iii)   0.3, 0.55, 0.80, 1.05, ...
        Given arithmetic series 0.3, 0.55, 0.80, 1.05, ...
        It is seen that, it's of the form of a, a + d, a + 2d, a + 3d,
        Thus, by comparing we get,
        a = 0.3, a + d = 0.55, a + 2d = 0.80, a + 3d = 1.05
        First term (a) = 0.3.
        By subtracting first term from second term. We get
        d = (a + d) - (a)
        d = 0.55 - 0.3
        d = 0.25
        ⇒ Common difference (d) = 0.25

(iv)   –1.1, – 3.1, – 5.1, –7.1, ...
         General series is –1.1, – 3.1, – 5.1, –7.1, ...
         It is seen that, it's of the form of a, a + d, a + 2d, a + 3d, ...
         Thus, by comparing these two, we get
         a = –1.1, a + d = –3.1, a + 2d = –5.1, a + 3d = –7.1
         First term (a) = –1.1
         Common difference (d) = (a + d) - (a)
         = -3.1 – (– 1.1)
         ⇒ Common difference (d) = – 2

2. Write the arithmetic progression when first term a and common difference d are as follows:
(i) a = 4, d = – 3
(ii) a = –1, d = 1/2
(iii) a = –1.5, d = – 0.5
Solution:

We know that, if first term (a) = a and common difference = d, then the arithmetic series is: a, a + d, a + 2d, a + 3d,
(i)   a = 4, d = -3
         Given, first term (a) = 4
         Common difference (d) = -3
         Then arithmetic progression is: a, a + d, a + 2d, a + 3d, ...
         ⇒4, 4 - 3, 4 + 2(-3), 4 + 3(-3), ...
         ⇒ 4, 1, – 2, – 5, – 8 ....

(ii)   a = -1, d = 1/2
         Given, first term (a) = -1
         Common difference (d) = 1/2
         Then arithmetic progression is: a, a + d, a + 2d, a + 3d,
         ⇒ -1, -1 + 1/2, -1 + 2½, -1 + 3½, ...
         ⇒ -1, -1/2, 0, 1/2

(iii)   a = –1.5, d = – 0.5
         Given First term (a) = –1.5
         Common difference (d) = – 0.5
         Then arithmetic progression is; a, a + d, a + 2d, a + 3d, ...
         ⇒ -1.5, -1.5 + (-0.5), –1.5 + 2(– 0.5), –1.5 + 3(– 0.5)
         ⇒ – 1.5, – 2, – 2.5, – 3, ...

3. In which of the following situations, the sequence of numbers formed will form an A.P.?
(i) The cost of digging a well for the first metre is Rs 150 and rises by Rs 20 for each succeeding metre.
(ii) The amount of air present in the cylinder when a vacuum pump removes each time 1/4 of their remaining in the cylinder.
(iii) Divya deposited Rs 1000 at compound interest at the rate of 10% per annum. The amount at

the end of first year, second year, third year, …, and so on.
Solution:

(i)   Given,

Cost of digging a well for the first meter (c_1) = Rs.150.
And, the cost rises by Rs.20 for each succeeding meter
Then,
Cost of digging for the second meter (c_2) = Rs.150 + Rs 20 = Rs 170
Cost of digging for the third meter (c_3) = Rs.170 + Rs 20 = Rs 210
Hence, its clearly seen that the costs of digging a well for different lengths are 150, 170, 190, 210, ...
Evidently, this series is in A·P.
With first term (a) = 150, common difference (d) = 20

(ii)   Given,

Let the initial volume of air in a cylinder be V liters each time $3^{th}/4$ of air in a remaining i.e
$1 - 1/4$
First time, the air in cylinder is V.
Second time, the air in cylinder is 3/4 V.
Third time, the air in cylinder is $(3/4)^2$ V.
Thus, series is V, 3/4 V, $(3/4)^2$ V,$(3/4)^3$ V, ...
Hence, the above series is not a A.P.

(iii)   Given,

Divya deposited Rs 1000 at compound interest of 10% p.a
So, the amount at the end of first year is = 1000 + 0.1(1000) = Rs 1100
And, the amount at the end of second year is = 1100 + 0.1(1100) = Rs 1210
And, the amount at the end of third year is = 1210 + 0.1(1210) = Rs 1331
Cleary, these amounts 1100, 1210 and 1331 are not in an A.P since the difference between them is not the same.

Exercise 9.4   Page No: 9.24

1. Find:
(i) 10th tent of the AP 1, 4, 7, 10....
(ii) 18th term of the AP √2, 3√2, 5√2, …….
(iii) nth term of the AP 13, 8, 3, -2, ...
(iv) 10th term of the AP -40, -15, 10, 35, ...
(v) 8th term of the AP 11, 104, 91, 78, ...
(vi) 11th tenor of the AP 10.0, 10.5, 11.0, 11.2, ...
(vii) 9th term of the AP 3/4, 5/4, 7/4 + 9/4, ...
Solution:

(i)   Given A.P. is 1, 4, 7, 10, ...
       First term (a) = 1
       Common difference (d) = Second term - First term
                            = 4 - 1 = 3.
       We know that, n^{th} term in an A.P = a + (n - 1)d
       Then, 10th term in the A.P is 1 + (10 - 1)3
       = 1 + 9x3
       = 1 + 27
       = 28
       ∴ 10th term of A. P. is 28

(ii)   Given A.P. is √2, 3√2, 5√2, …….
       First term (a) = √2
       Common difference = Second term – First term
                        = 3√2 - √2
       ⇒   d = 2√2
       We know that, n^{th} term in an A. P. = a + (n - 1)d
       Then, 18th term of A. P. = √2 + (18 - 1)2√2
       = √2 + 17.2√2
       = √2 (1+34)
       = 35√2
       ∴ 18th term of A. P. is 35√2

(iii) Given A. P. is 13, 8, 3, - 2, ...
       First term (a) = 13
       Common difference (d) = Second term first term
                            = 8 - 13 = – 5
       We know that, n^{th} term of an A.P. a_n = a +(n - 1)d
       = 13 + (n - 1) - 5
       = 13 - 5n + 5
       ∴ n^{th} term of the A.P is a_n = 18 - 5n

(iv)   Given A. P. is - 40, -15, 10, 35, ...
       First term (a) = -40

Common difference (d) = Second term - fast term
$$= -15 - (- 40)$$
$$= 40 - 15$$
$$= 25$$
We know that, n^{th} term of an A.P. $a_n = a + (n - 1)d$
Then, 10th term of A. P. $a_{10} = -40 + (10 - 1)25$
$$= - 40 + 9.25$$
$$= - 40 + 225$$
$$= 185$$
$\therefore 10^{th}$ term of the A. P. is 185

(v)   Given sequence is 117, 104, 91, 78, ...
First term (a) = 117
Common difference (d) = Second term - first term
$$= 104 - 117$$
$$= - 13$$
We know that, n^{th} term = $a + (n - 1)d$
Then, 8th term = $a + (8 - 1)d$
$$= 117 + 7(-13)$$
$$= 117 - 91$$
$$= 26$$
$\therefore 8^{th}$ term of the A. P. is 26

(vi)   Given A. P is 10.0, 10.5, 11.0, 11.5,
First term (a) = 10.0
Common difference (d) = Second term - first term
$$= 10.5 - 10.0 = 0.5$$
We know that, n^{th} term $a_n = a + (n - 1)d$
Then, 11th term $a_{11} = 10.0 + (11 - 1)0.5$
$$= 10.0 + 10 \times 0.5$$
$$= 10.0 + 5$$
$$=15.0$$
$\therefore 11^{th}$ term of the A. P. is 15.0

(vii)   Given A. P is 3/4, 5/4, 7/4, 9/4, ...
First term (a) = 3/4
Common difference (d) = Second term - first term
$$= 5/4 - 3/4$$
$$= 2/4$$
We know that, n^{th} term $a_n = a + (n - 1)d$
Then, 9th term $a_9 = a + (9 - 1)d$

$$= \frac{3}{4} + 8.\frac{2}{4}$$

$$= \frac{3}{4} + \frac{16}{4}$$

$$= \frac{19}{4}$$

∴ 9th term of the A. P. is 19/4.

2.(i) Which term of the AP 3, 8, 13, ... is 248?
(ii) Which term of the AP 84, 80, 76, ... is 0?
(iii) Which term of the AP 4. 9, 14, ... is 254?
(iv) Which term of the AP 21. 42, 63, 84, ... is 420?
(v) Which term of the AP 121, 117. 113, ... is its first negative term?
Solution:

(i)   Given A.P. is 3, 8, 13, ...
        First term (a) = 3
        Common difference (d) = Second term - first term
        = 8 - 3
        = 5
        We know that, n^{th} term (a_n) = a + (n - 1)d
        And, given n^{th} term a_n = 248
        248 = 3+(n - 1)5
        248 = -2 + 5n
        5n = 250
        n =250/5 = 50
        ∴ 50th term in the A.P is 248.

(ii)   Given A. P is 84, 80, 76, ...
        First term (a) = 84
        Common difference (d) = a_2 - a
        = 80 - 84
        = – 4
        We know that, n^{th} term (a_n) = a +(n - 1)d
        And, given nth term is 0
        0 = 84 + (n - 1) - 4
        84 = +4(n - 1)
        n - 1 = 84/4 = 21
        n = 21 + 1 = 22
        ∴ 22nd term in the A.P is 0.

(iii)   Given A. P 4, 9, 14, ...

First term (a) = 4
Common difference (d) = $a_2 - a_1$
= 9 - 4
= 5
We know that, n^{th} term $(a_n) = a + (n - 1)d$
And, given n^{th} term is 254
4 + (n - 1)5 = 254
(n - 1)·5 = 250
n - 1 = 250/5 = 50
n = 51
∴ 51th term in the A.P is 254.

(iv)   Given A. P 21, 42, 63, 84, ...
        a = 21, d = $a_2 - a_1$
                  = 42 - 21
                  = 21
        We know that, n^{th} term $(a_n) = a +(n - 1)d$
        And, given n^{th} term = 420
        21 + (n - 1)21 = 420
        (n - 1)21 = 399
        n - 1 = 399/21 = 19
        n = 20
        ∴ 20th term is 420.

(v)   Given A.P is 121, 117, 113, ...
        Fiat term (a) = 121
        Common difference (d) = 117 - 121
                                = - 4
        We know that, n^{th} term $a_n = a + (n - 1)d$
        And, for some n^{th} term is negative i.e., $a_n < 0$
        121 + (n - 1) - 4 < 0
        121 + 4 - 4n < 0
        125 - 4n < 0
        4n > 125
        n > 125/4
        n > 31.25
        The integer which comes after 31.25 is 32.
        ∴ 32nd term in the A.P will be the first negative term.

3.(i) Is 68 a term of the A.P. 7, 10, 13,… ?
(ii) Is 302 a term of the A.P. 3, 8, 13, …. ?
(iii) Is -150 a term of the A.P. 11, 8, 5, 2, … ?
Solutions:

(i)   Given, A.P. 7, 10, 13,…
        Here, a = 7 and d = $a_2 - a_1$ = 10 - 7 = 3

We know that, n^{th} term $a_n = a + (n - 1)d$
Required to check n^{th} term $a_n = 68$
$a + (n - 1)d = 68$
$7 + (n - 1)3 = 68$
$7 + 3n – 3 = 68$
$3n + 4 = 68$
$3n = 64$
$\Rightarrow n = 64/3$, which is not a whole number.
Therefore, 68 is not a term in the A.P.

(ii)   Given, A.P. 3, 8, 13,…
        Here, $a = 3$ and $d = a_2 – a_1 = 8 – 3 = 5$
        We know that, n^{th} term $a_n = a + (n - 1)d$
        Required to check n^{th} term $a_n = 302$
        $a + (n - 1)d = 302$
        $3 + (n - 1)5 = 302$
        $3 + 5n – 5 = 302$
        $5n - 2 = 302$
        $5n = 304$
        $\Rightarrow n = 304/5$, which is not a whole number.
        Therefore, 302 is not a term in the A.P.

(iii)   Given, A.P. 11, 8, 5, 2, …
        Here, $a = 11$ and $d = a_2 – a_1 = 8 – 11 = -3$
        We know that, n^{th} term $a_n = a + (n - 1)d$
        Required to check n^{th} term $a_n = -150$
        $a + (n - 1)d = -150$
        $11 + (n - 1)(-3) = -150$
        $11 – 3n + 3 = -150$
        $3n = 150 + 14$
        $3n = 164$
        $\Rightarrow n = 164/3$, which is not a whole number.
        Therefore, -150 is not a term in the A.P.

4. How many terms are there in the A.P.?
(i) 7, 10, 13, ….., 43
(ii) -1, -5/6, -2/3, -1/2, … , 10/3
(iii) 7, 13, 19, …, 205
(iv) 18, 15½, 13, …., -47
Solution:

(i)   Given, A.P. 7, 10, 13, ….., 43
        Here, $a = 7$ and $d = a_2 – a_1 = 10 – 7 = 3$
        We know that, n^{th} term $a_n = a + (n - 1)d$
        And, given n^{th} term $a_n = 43$

a + (n - 1)d = 43
7 + (n - 1)(3) = 43
7 + 3n – 3 = 43
3n = 43 – 4
3n = 39
⇒ n = 13
Therefore, there are 13 terms in the given A.P.

(ii)   Given, A.P. -1, -5/6, -2/3, -1/2, … , 10/3
        Here, a = -1 and d = $a_2 - a_1$ = -5/6 – (-1) = 1/6
        We know that, n^{th} term a_n = a + (n - 1)d
        And, given n^{th} term a_n = 10/3
        a + (n - 1)d = 10/3
        -1 + (n - 1)(1/6) = 10/3
        -1 + n/6 – 1/6 = 10/3
        n/6 = 10/3 + 1 + 1/6
        n/6 = (20 + 6 + 1)/6
        n = (20 + 6 + 1)
        ⇒ n = 27
        Therefore, there are 27 terms in the given A.P.

(iii)   Given, A.P. 7, 13, 19, …, 205
        Here, a = 7 and d = $a_2 - a_1$ = 13 – 7 = 6
        We know that, n^{th} term a_n = a + (n - 1)d
        And, given n^{th} term a_n = 205
        a + (n - 1)d = 205
        7 + (n - 1)(6) = 205
        7 + 6n – 6 = 205
        6n = 205 – 1
        n = 204/6
        ⇒ n = 34
        Therefore, there are 34 terms in the given A.P.

(iv)   Given, A.P. 18, 15½, 13, …., -47
        Here, a = 7 and d = $a_2 - a_1$ = 15½ – 18 = 5/2
        We know that, n^{th} term a_n = a + (n - 1)d
        And, given n^{th} term a_n = -47
        a + (n - 1)d = 43
        18 + (n - 1)(-5/2) = -47
        18 – 5n/2 + 5/2 = -47
        36 – 5n + 5 = -94
        5n = 94 + 36 + 5
        5n = 135
        ⇒ n = 27
        Therefore, there are 27 terms in the given A.P.

5. The first term of an A.P. is 5, the common difference is 3 and the last term is 80; find the number of terms.
Solution:

Given,
$a = 5$ and $d = 3$
We know that, n^{th} term $a_n = a + (n - 1)d$
So, for the given A.P. $a_n = 5 + (n - 1)3 = 3n + 2$
Also given, last term = 80
$\Rightarrow 3n + 2 = 80$
$3n = 78$
$n = 78/3 = 26$
Therefore, there are 26 terms in the A.P.

6. The 6th and 17th terms of an A.P. are 19 and 41 respectively, find the 40th term.
Solution:

Given,
$a_6 = 19$ and $a_{17} = 41$
We know that, n^{th} term $a_n = a + (n - 1)d$
So,
$a_6 = a + (6-1)d$
$\Rightarrow a + 5d = 19$ …… (i)
Similarity,
$a_{17} = a + (17 - 1)d$
$\Rightarrow a + 16d = 41$ …… (ii)
Solving (i) and (ii),
(ii) – (i) $\Rightarrow$
$a + 16d – (a + 5d) = 41 – 19$
$11d = 22$
$\Rightarrow d = 2$
Using d in (i), we get
$a + 5(2) = 19$
$a = 19 – 10 = 9$

Now, the 40th term is given by $a_{40} = 9 + (40 - 1)2 = 9 + 78 = 87$
Therefore the 40th term is 87.

7. If 9th term of an A.P. is zero, prove its 29th term is double the 19th term.
Solution:

Given,
$a_9 = 0$
We know that, n^{th} term $a_n = a + (n - 1)d$
So, $a + (9 - 1)d = 0 \Rightarrow a + 8d = 0$ ……(i)
Now,

29th term is given by $a_{29} = a + (29 - 1)d$
$\Rightarrow a_{29} = a + 28d$
And, $a_{29} = (a + 8d) + 20d$ [using (i)]
$\Rightarrow a_{29} = 20d$ ….. (ii)

Similarly, 19th term is given by $a_{19} = a + (19 - 1)d$
$\Rightarrow a_{19} = a + 18d$
And, $a_{19} = (a + 8d) + 10d$ [using (i)]
$\Rightarrow a_{19} = 10d$ …..(iii)

On comparing (ii) and (iii), it's clearly seen that
$a_{29} = 2(a_{19})$

Therefore, 29th term is double the 19th term.

8. If 10 times the 10th term of an A.P. is equal to 15 times the 15th term, show that 25th term of the A.P. is zero.
Solution:

Given,
10 times the 10th term of an A.P. is equal to 15 times the 15th term.
We know that, n^{th} term $a_n = a + (n - 1)d$
$\Rightarrow 10(a_{10}) = 15(a_{15})$
$10(a + (10 - 1)d) = 15(a + (15 - 1)d)$
$10(a + 9d) = 15(a + 14d)$
$10a + 90d = 15a + 210d$
$5a + 120d = 0$
$5(a + 24d) = 0$
$a + 24d = 0$
$a + (25 - 1)d = 0$
$\Rightarrow a_{25} = 0$
Therefore, the 25th term of the A.P. is zero.

9. The 10th and 18th terms of an A.P. are 41 and 73 respectively. Find 26th term.
Solution:

Given,
$A_{10} = 41$ and $a_{18} = 73$
We know that, n^{th} term $a_n = a + (n - 1)d$
So,
$a_{10} = a + (10 - 1)d$
$\Rightarrow a + 9d = 41$ …… (i)
Similarity,
$a_{18} = a + (18 - 1)d$
$\Rightarrow a + 17d = 73$ …… (ii)
Solving (i) and (ii),

(ii) – (i) ⇒
a + 17d – (a + 9d) = 73 – 41
8d = 32
⇒ d = 4
Using d in (i), we get
a + 9(4) = 41
a = 41 – 36 = 5

Now, the 26th term is given by a_{26} = 5 + (26 - 1)4 = 5 + 100 = 105
Therefore the 26th term is 105.

10. In a certain A.P. the 24th term is twice the 10th term. Prove that the 72nd term is twice the 34th term.
Solution:

Given,
24th term is twice the 10th term.
We know that, n^{th} term a_n = a + (n - 1)d
⇒ a_{24} = 2(a_{10})
a + (24 - 1)d = 2(a + (10 - 1)d)
a + 23d = 2(a + 9d)
a + 23d = 2a + 18d
a = 5d …. (1)

Now, the 72nd term can be expressed as
a_{72} = a + (72 - 1)d
= a + 71d
= a + 5d + 66d
= a + a + 66d   [using (1)]
= 2(a + 33d)
= 2(a + (34 - 1)d)
= 2(a_{34})
⇒ a_{72} = 2(a_{34})
Hence, the 72nd term is twice the 34th term of the given A.P.

11. The 26th, 11th and the last term of an A.P. are 0, 3 and -1/5, respectively. Find the common difference and the number of terms.
Solution:

Given,
a_{26} = 0 , a_{11} = 3 and a_n (last term) = -1/5 of an A.P.
We know that, n^{th} term a_n = a + (n - 1)d
Then,
a_{26} = a + (26 - 1)d
⇒ a + 25d = 0 …..(1)

And,
$a_{11} = a + (11 - 1)d$
$\Rightarrow a + 10d = 3$ …… (2)

Solving (1) and (2),
(1) – (2) $\Rightarrow$
$a + 25d - (a + 10d) = 0 - 3$
$15d = -3$
$\Rightarrow d = -1/5$
Using d in (1), we get
$a + 25(-1/5) = 0$
$a = 5$

Now, given that the last term $a_n = -1/5$
$\Rightarrow 5 + (n - 1)(-1/5) = -1/5$
$5 + -n/5 + 1/5 = -1/5$
$25 - n + 1 = -1$
$n = 27$
Therefore, the A.P has 27 terms and its common difference is -1/5.

12. If the nth term of the A.P. 9, 7, 5, …. is same as the nth term of the A.P. 15, 12, 9, … find n.
Solution:

Given,
$A.P_1 = 9, 7, 5, ….$ and $A.P_2 = 15, 12, 9, …$
And, we know that, n^{th} term $a_n = a + (n - 1)d$

For $A.P_1$,
$a = 9$, $d =$ Second term – first term $= 9 - 7 = -2$
And, its nth term $a_n = 9 + (n - 1)(-2) = 9 - 2n + 2$
        $a_n = 11 - 2n$ …..(i)
Similarly, for $A.P_2$
$a = 15$, $d =$ Second term – first term $= 12 - 15 = -3$
And, its nth term $a_n = 15 + (n - 1)(-3) = 15 - 3n + 3$
        $a_n = 18 - 3n$ …..(ii)

According to the question, its given that
n^{th} term of the $A.P_1 = n^{th}$ term of the $A.P_2$
$\Rightarrow 11 - 2n = 18 - 3n$
$n = 7$
Therefore, the 7th term of the both the A.Ps are equal.

13. Find the 12th term from the end of the following arithmetic progressions:
(i) 3, 5, 7, 9, …. 201
(ii) 3,8,13, … ,253
(iii) 1, 4, 7, 10, … ,88

Solution:

In order the find the 12th term for the end of an A.P. which has n terms, its done by simply finding the $((n -12) + 1)^{th}$ of the A.P
And we know, nth term a_n = a + (n - 1)d

(i)   Given A.P = 3, 5, 7, 9, …. 201
       Here, a = 3 and d = (5 - 3) = 2
       Now, find the number of terms when the last term is known i.e, 201
       a_n = 3 + (n - 1)2 = 201
       3 + 2n – 2 = 201
       2n = 200
       n = 100
       Hence, the A.P has 100 terms.

       So, the 12th term from the end is same as $(100 – 12 + 1)^{th}$ of the A.P which is the 89th term.
       ⇒ a_{89} = 3 + (89 - 1)2
               = 3 + 88(2)
               = 3 + 176
               = 179
       Therefore, the 12th term from the end of the A.P is 179.

(ii)   Given A.P = 3,8,13, … ,253
       Here, a = 3 and d = (8 - 3) = 5
       Now, find the number of terms when the last term is known i.e, 253
       a_n = 3 + (n - 1)5 = 253
       3 + 5n – 5 = 253
       5n = 253 + 2 = 255
       n = 255/5
       n = 51
       Hence, the A.P has 51 terms.

       So, the 12th term from the end is same as $(51 – 12 + 1)^{th}$ of the A.P which is the 40th term.
       ⇒ a_{40} = 3 + (40 - 1)5
               = 3 + 39(5)
               = 3 + 195
               = 198
       Therefore, the 12th term from the end of the A.P is 198.

(iii) Given A.P = 1, 4, 7, 10, … ,88
       Here, a = 1 and d = (4 - 1) = 3
       Now, find the number of terms when the last term is known i.e, 88
       a_n = 1 + (n - 1)3 = 88
       1 + 3n – 3 = 88
       3n = 90
       n = 30

Hence, the A.P has 30 terms.

So, the 12th term from the end is same as $(30 - 12 + 1)^{th}$ of the A.P which is the 19th term.

$\Rightarrow a_{89}$ = 1 + (19 - 1)3
   = 1 + 18(3)
   = 1 + 54
   = 55

Therefore, the 12th term from the end of the A.P is 55.

14. The 4th term of an A.P. is three times the first and the 7th term exceeds twice the third term by 1. Find the first term and the common difference.
Solution:

Let's consider the first term and the common difference of the A.P to be a and d respectively.
Then, we know that $a_n = a + (n - 1)d$
Given conditions,
4th term of an A.P. is three times the first
Expressing this by equation we have,
$\Rightarrow a_4 = 3(a)$
a + (4 - 1)d = 3a
3d = 2a $\Rightarrow$ a = 3d/2.......(i)
And,
7th term exceeds twice the third term by 1
$\Rightarrow a_7 = 2(a_3) + 1$
a + (7 – 1)d = 2(a + (3–1)d) + 1
a + 6d = 2a + 4d + 1
a – 2d +1 = 0 ….. (ii)

Using (i) in (ii), we have
3d/2 – 2d + 1 = 0
3d – 4d + 2 = 0
d = 2
So, putting d = 2 in (i), we get a
$\Rightarrow$ a = 3

Therefore, the first term is 3 and the common difference is 2.

15. Find the second term and the nth term of an A.P. whose 6th term is 12 and the 8th term is 22.
Solution:

Given, in an A.P
a_6 = 12 and a_8 = 22
We know that $a_n = a + (n - 1)d$
So,
a_6 = a + (6-1)d = a + 5d = 12 …. (i)
And,

$a_8 = a + (8-1)d = a + 7d = 22$ ……. (ii)

Solving (i) and (ii), we have
(ii) - (i) $\Rightarrow$
$a + 7d – (a + 5d) = 22 – 12$
$2d = 10$
$d = 5$
Putting d in (i) we get,
$a + 5(5) = 12$
$a = 12 – 25$
$a = -13$
Thus, for the A.P: $a = -13$ and $d = 5$
So, the nth term is given by $a_n = a + (n-1)d$
$a_n = -13 + (n-1)5 = -13 + 5n – 5$
$\Rightarrow a_n = 5n – 18$
Hence, the second term is given by $a_2 = 5(2) – 18 = 10 – 18 = -8$

16. How many numbers of two digit are divisible by 3?
Solution:

The first 2 digit number divisible by 3 is 12. And, the last 2 digit number divisible by 3 is 99.
So, this forms an A.P.
12, 15, 18, 21, …. , 99
Where, $a = 12$ and $d = 3$
Finding the number of terms in this A.P
$\Rightarrow 99 = 12 + (n-1)3$
$99 = 12 + 3n – 3$
$90 = 3n$
$n = 90/3 = 30$
Therefore, there are 30 two digit numbers divisible by 3.

17. An A.P. consists of 60 terms. If the first and the last terms be 7 and 125 respectively, find 32nd term.
Solution:

Given, an A.P of 60 terms
And, $a = 7$ and $a_{60} = 125$
We know that $a_n = a + (n - 1)d$
$\Rightarrow a_{60} = 7 + (60 - 1)d = 125$
$7 + 59d = 125$
$59d = 118$
$d = 2$

So, the 32nd term is given by
$a_{32} = 7 + (32 -1)2 = 7 + 62 = 69$

$\Rightarrow a_{32} = 69$

18. The sum of 4th and 8th terms of an A.P. is 24 and the sum of the 6th and 10th terms is 34. Find the first term and the common difference of the A.P.
Solution:

Given, in an A.P
The sum of 4th and 8th terms of an A.P. is 24
$\Rightarrow a_4 + a_8 = 24$
And, we know that $a_n = a + (n - 1)d$
$[a + (4-1)d] + [a + (8-1)d] = 24$
$2a + 10d = 24$
$a + 5d = 12$ …. (i)

Also given that,
the sum of the 6th and 10th terms is 34
$\Rightarrow a_6 + a_{10} = 34$
$[a + 5d] + [a + 9d] = 34$
$2a + 14d = 34$
$a + 7d = 17$ …… (ii)

Subtracting (i) form (ii), we have
$a + 7d – (a + 5d) = 17 – 12$
$2d = 5$
$d = 5/2$
Using d in (i) we get,
$a + 5(5/2) = 12$
$a = 12 – 25/2$
$a = -1/2$

Therefore, the first term is -1/2 and the common difference is 5/2.

19. The first term of an A.P. is 5 and its 100th term is -292. Find the 50th term of this A.P.
Solution:

Given, an A.P whose
$a = 5$ and $a_{100} = -292$
We know that $a_n = a + (n - 1)d$
$a_{100} = 5 + 99d = -292$
$99d = -297$
$d = -3$

Hence, the 50th term is
$a_{50} = a + 49d = 5 + 49(-3) = 5 – 147 = -142$

20. Find $a_{30} - a_{20}$ for the A.P.
(i) -9, -14, -19, -24   **(ii) a, a+d, a+2d, a+3d, ……**
Solution:

      We know that a_n = a + (n - 1)d
      So, $a_{30} - a_{20}$ = (a + 29d) – (a + 19) =10d

      (i)   Given A.P. -9, -14, -19, -24
                Here, a = -9 and d = -14 – (-9) = = -14 + 9 = -5
                So, $a_{30} - a_{20}$ = 10d
                            = 10(-5)
                            = -50
      (ii)   Given A.P. a, a+d, a+2d, a+3d, ……
                So, $a_{30} - a_{20}$ = (a + 29d) – (a + 19d)
                        =10d

21. Write the expression $a_n - a_k$ for the A.P. a, a+d, a+2d, …..
Hence, find the common difference of the A.P. for which
(i) 11th term is 5 and 13th term is 79.
(ii) $a_{10} - a_5$ = 200
(iii) 20th term is 10 more than the 18th term.
Solution:

      Given A.P. a, a+d, a+2d, …..
      So, a_n = a + (n-1)d = a + nd –d
      And, a_k = a + (k-1)d = a + kd – d
      a_n - a_k = (a + nd – d) – (a + kd – d)
           = (n – k)d

      (i)   Given 11th term is 5 and 13th term is 79,
                Here n = 13 and k = 11,
                $a_{13} - a_{11}$ = (13 – 11)d = 2d
                ⇒ 79 – 5 = 2d
                d = 74/2 = 37

      (ii)   Given, $a_{10} - a_5$ = 200
                ⇒ (10 - 5)d = 200
                5d = 200
                d = 40

      (iii)   Given, 20th term is 10 more than the 18th term.
                ⇒ $a_{20} - a_{18}$ = 10
                (20 - 18)d = 10
                2d = 10
                d = 5

22. Find n if the given value of x is the nth term of the given A.P.
(i) 25, 50, 75, 100,   ; x = 1000   **(ii) -1, -3, -5, -7, …; x = -151**
(iii) 5½, 11, 16½, 22, ….; x = 550   **(iv) 1, 21/11, 31/11, 41/11, …; x = 171/11**
Solution:

(i)   Given A.P. 25, 50, 75, 100, …… ,1000
        Here, a = 25 d = 50 – 25 = 25
        Last term (nth term) = 1000
        We know that a_n = a + (n - 1)d
        ⇒ 1000 = 25 + (n-1)25
        1000 = 25 + 25n – 25
        n = 1000/25
        n = 40

(ii)   Given A.P. -1, -3, -5, -7, …., -151
        Here, a = -1 d = -3 – (-1) = -2
        Last term (nth term) = -151
        We know that a_n = a + (n - 1)d
        ⇒ -151 = -1 + (n-1)(-2)
        -151 = -1 - 2n + 2
        n = 152/2
        n = 76

(iii)   Given A.P. 5½, 11, 16½, 22, … , 550
        Here, a = 5½ d = 11 – (5½) = 5½ = 11/2
        Last term (nth term) = 550
        We know that a_n = a + (n - 1)d
        ⇒ 550 = 5½ + (n-1)(11/2)
        550 x 2 = 11+ 11n – 11
        1100 = 11n
        n = 100

(iv)   Given A.P. 1, 21/11, 31/11, 41/11, 171/11
        Here, a = 1 d = 21/11 – 1 = 10/11
        Last term (nth term) = 171/11
        We know that a_n = a + (n - 1)d
        ⇒ 171/11 = 1 + (n-1)10/11
        171 = 11 + 10n – 10
        n = 170/10
        n = 17

23. The eighth term of an A.P is half of its second term and the eleventh term exceeds one third of its fourth term by 1. Find the 15th term.
Solution:

        Given, an A.P in which,

$a_8 = 1/2(a_2)$
$a_{11} = 1/3(a_4) + 1$
We know that $a_n = a + (n - 1)d$
$\Rightarrow a_8 = 1/2(a_2)$
$a + 7d = 1/2(a + d)$
$2a + 14d = a + d$
$a + 13d = 0$ …… (i)

And, $a_{11} = 1/3(a_4) + 1$
$a + 10d = 1/3(a + 3d) + 1$
$3a + 30d = a + 3d + 3$
$2a + 27d = 3$ …… (ii)

Solving (i) and (ii), by (ii) – 2x(i) $\Rightarrow$
$2a + 27d – 2(a + 13d) = 3 - 0$
$d = 3$
Putting d in (i) we get,
$a + 13(3) = 0$
$a = -39$

Thus, the 15th term $a_{15} = -39 + 14(3) = -39 + 42 = 3$

24. Find the arithmetic progression whose third term is 16 and the seventh term exceeds its fifth term by 12.
Solution:

Given, in an A.P
$a_3 = 16$ and $a_7 = a_5 + 12$
We know that $a_n = a + (n - 1)d$
$\Rightarrow a + 2d = 16$…… (i)
And,
$a + 6d = a + 4d + 12$
$2d = 12$
$\Rightarrow d = 6$

Using d in (i), we have
$a + 2(6) = 16$
$a = 16 – 12 = 4$

Hence, the A.P is 4, 10, 16, 22, …….

25. The 7th term of an A.P. is 32 and its 13th term is 62. Find the A.P.
Solution:

Given,
$a_7 = 32$ and $a_{13} = 62$

From $a_n - a_k = (a + nd - d) - (a + kd - d)$

$= (n - k)d$

$a_{13} - a_7 = (13 - 7)d = 62 - 32 = 30$
$6d = 30$
$d = 5$

Now,
$a_7 = a + (7 - 1)5 = 32$
$a + 30 = 32$
$a = 2$

Hence, the A.P is 2, 7, 12, 17, ……

26. Which term of the A.P. 3, 10, 17, …. will be 84 more than its 13ᵗʰ term ?
Solution:

Given, A.P. 3, 10, 17, ….
Here, $a = 3$ and $d = 10 - 3 = 7$
According the question,
$a_n = a_{13} + 84$
Using $a_n = a + (n - 1)d$,
$3 + (n - 1)7 = 3 + (13 - 1)7 + 84$
$3 + 7n - 7 = 3 + 84 + 84$
$7n = 168 + 7$
$n = 175/7$
$n = 25$

Therefore, it the 25ᵗʰ term which is 84 more than its 13ᵗʰ term.

27. Two arithmetic progressions have the same common difference. The difference between their 100ᵗʰ terms is 100, what is the difference between their 1000ᵗʰ terms?
Solution:

Let the two A.Ps be A.P₁ and A.P₂
For A.P₁ the first term = a and the common difference = d
And for A.P₂ the first term = b and the common difference = d
So, from the question we have
$a_{100} - b_{100} = 100$
$(a + 99d) - (b + 99d) = 100$
$a - b = 100$

Now, the difference between their 1000ᵗʰ terms is,
$(a + 999d) - (b + 999d) = a - b = 100$

Therefore, the difference between their 1000ᵗʰ terms is also 100.

Exercise 9.5   Page No: 9.30

1. Find the value of x for which (8x + 4), (6x – 2) and (2x + 7) are in A.P.
Solution:

Given,
(8x + 4), (6x – 2) and (2x + 7) are in A.P.
So, the common difference between the consecutive terms should be the same.
(6x – 2) – (8x + 4) = (2x + 7) – (6x – 2)
⇒ 6x – 2 – 8x – 4 = 2x + 7 – 6x + 2
⇒ -2x – 6 = -4x + 9
⇒ -2x + 4x = 9 + 6
⇒ 2x = 15
Therefore, x = 15/2

2. If x + 1, 3x and 4x + 2 are in A.P., find the value of x.
Solution:

Given,
x + 1, 3x and 4x + 2 are in A.P.
So, the common difference between the consecutive terms should be the same.
3x – x – 1 = 4x + 2 – 3x
⇒ 2x – 1 = x + 2
⇒ 2x – x = 2 + 1
⇒ x = 3
Therefore, x = 3

3. Show that (a – b)², (a² + b²) and (a + b)² are in A.P.
Solution:

If (a – b)², (a² + b²) and (a + b)² have to be in A.P. then,
It should satisfy the condition,
2b = a + c [for a, b, c are in A.P]
Thus,
2 (a² + b²) = (a – b)² + (a + b)²
2 (a² + b²) = a² + b² – 2ab + a² + b² + 2ab
2 (a² + b²) = 2a² + 2b² = 2 (a² + b²)
LHS = RHS
Hence proved.

4. The sum of three terms of an A.P. is 21 and the product of the first and the third terms exceeds the second term by 6, find three terms.
Solution:

Let's consider the three terms of the A.P. to be a – d, a, a + d
so, the sum of three terms = 21

$\Rightarrow$ a – d + a + a + d = 21
$\Rightarrow$ 3a = 21
$\Rightarrow$ a = 7

And, product of the first and 3rd = 2nd term + 6
$\Rightarrow$ (a – d) (a + d) = a + 6
a² – d² = a + 6
$\Rightarrow$ (7)² – d² = 7 + 6
$\Rightarrow$ 49 – d² = 13
$\Rightarrow$ d² = 49 – 13 = 36
$\Rightarrow$ d² = (6)²
$\Rightarrow$ d = 6

Hence, the terms are 7 – 6, 7, 7 + 6 $\Rightarrow$ 1, 7, 13

5. Three numbers are in A.P. If the sum of these numbers be 27 and the product 648, find the numbers.
Solution:

Let the three numbers of the A.P. be a – d, a, a + d
From the question,
Sum of these numbers = 27
a – d + a + a + d = 27
$\Rightarrow$ 3a = 27
a = 27/3 = 9

Now, product of these numbers = 648
(a - d)(a)(a + d) = 648
$a(a^2 - d^2) = 648$
$a^2 - 648/a = d^2$
$9^2 - (648/9) = d^2$
$9^3 - 648 = 9d^2$
$729 - 648 = 9d^2$
$81 = 9d^2$
$d^2 = 9$
d = 3 or -3

Hence, the terms are 9-3, 9 and 9+3 $\Rightarrow$ 6, 9, 12 or 12, 9, 6 (for d = -3)

6. Find the four numbers in A.P., whose sum is 50 and in which the greatest number is 4 times the least.
Solution:

Let's consider the four terms of the A.P. to be (a – 3d), (a – d), (a + d) and (a + 3d).
From the question,
Sum of these terms = 50

⇒ (a − 3d) + (a − d) + (a + d) + (a + 3d) = 50
⇒ a − 3d + a − d + a + d + a − 3d= 50
⇒ 4a = 50
⇒ a = 50/4 = 25/2
And, also given that the greatest number = 4 x least number
⇒ a + 3d = 4 (a − 3d)
⇒ a + 3d = 4a − 12d
⇒ 4a − a = 3d + 12d
⇒3a = 15d
⇒a = 5d
Using the value of a in the above equation, we have
⇒25/2 = 5d
⇒ d = 5/2

So, the terms will be:
(a − 3d) = (25/2 − 3(5/2)), (a − d) = (25/2 − 5/2), (25/2 + 5/2) and (25/2 + 3(5/2)).
⇒ 5, 10, 15, 20

Exercise 9.6   Page No: 9.50

1. Find the sum of the following arithmetic progressions:
(i) 50, 46, 42, ... to 10 terms
(ii) 1, 3, 5, 7, ... to 12 terms
(iii) 3, 9/2, 6, 15/2, ... to 25 terms
(iv) 41, 36, 31, ... to 12 terms
(v) a + b, a - b, a - 3b, ... to 22 terms
(vi) (x - y)², (x² + y²), (x + y)², to 22 tams

(vii) $\dfrac{x-y}{x+y}, \dfrac{3x-2y}{x+y}, \dfrac{5x-3y}{x+y}$, to n terms

(viii) – 26, – 24, – 22, ... to 36 terms
Solution:

In an A.P if the first term = a, common difference = d, and if there are n terms.
Then, sum of n terms is given by:

$S_n = \dfrac{n}{2}\{2a + (n - 1)d\}$

(i)   Given A.P. is 50, 46, 42 to 10 term.
         First term (a) = 50
         Common difference (d) = 46 - 50 = – 4
         n^{th} term (n) = 10

         Then $S_{10} = \dfrac{10}{2}\{2.50 + (10 - 1) - 4\}$

         = 5{100 - 9.4}
         = 5{100 - 36}
         = 5 × 64
         ∴ S_{10} = 320

(ii)   Given A.P is, 1, 3, 5, 7, ...to 12 terms.
         First term (a) = 1
         Common difference (d) = 3 - 1 = 2
         n^{th} term (n) = 12

         Sum of nth terms $S_{12} = \dfrac{12}{2} \times \{2.1 + (12 - 1).2\}$

         = 6 × {2 + 22} = 6.24
         ∴ S_{12} = 144

(iii)   Given A.P. is 3, 9/2, 6, 15/2, ... to 25 terms
         First term (a) = 3
         Common difference (d) = 9/2 - 3 = 3/2
         Sum of n terms S_n, given n = 25

$$S_{25} = \frac{n}{2}(2a + (n-1)d)$$

$$S_{25} = \frac{25}{2}(2.3 + 25 - 1) \times \frac{3}{2}$$

$$= \frac{25}{2}\left(6 + 24.\frac{3}{2}\right)$$

$$= \frac{25}{2}(6 + 36)$$

$$= \frac{25}{2}(42)$$

$$\therefore S_{25} = 525$$

(iv)   Given expression is 41, 36, 31, ….. to 12 terms.
First term (a) = 41
Common difference (d) = 36 - 41 = -5
Sum of n terms S_n, given n = 12

$$S_{12} = \frac{n}{2}(2a + (n-1)d)$$

$$S_{12} = \frac{12}{6}(2.41 + 12 - 1) \times -5$$

$$= 6\big(82 + 11 \times (-5)\big)$$

$$= 6 \times 27$$

$$= 162$$

$$\therefore \ S_{12} = 162.$$

(v)   a + b, a – b, a - 3b, ….. to 22 terms
First term (a) = a + b
Common difference (d) = a - b - a - b = -2b
Sum of n terms S_n = n/2{2a(n - 1). d}
Here n = 22
S_{22} = 22/2{2.(a + b) + (22 - 1). -2b}
= 11{2(a + b) - 22b)
= 11{2a - 20b}

$= 22a - 440b$

$\therefore S_{22} = 22a - 440b$

(vi) $(x - y)^2, (x^2 + y^2), (x + y)^2,...$ to n terms

First term $(a) = (x - y)^2$

Common difference $(d) = x^2 + y^2 - (x - y)^2$

$= x^2 + y^2 - (x^2 + y^2 - 2xy)$

$= x^2 + y^2 - x^2 + y^2 + 2xy$

$= 2xy$

Sum of nth terms $S_n = n/2\{2a + (n - 1). d\}$

$= n/2\{2(x - y)^2 + (n - 1). 2xy\}$

$= n\{(x - y)^2 + (n - 1)xy\}$

$\therefore S_n = n\{(x — y)^2 + (n — 1). xy)$

(vii) $\dfrac{x - y}{x + y}, \dfrac{3x - 2y}{x + y}, \dfrac{5x - 3y}{x + y}, \ldots\ldots$ to n terms

First term $(a) = \dfrac{x - y}{x + y}$

Common difference $(d) = \dfrac{3x - 2y}{x + y} - \dfrac{x - y}{x + y}$

$= \dfrac{3x - 2y - x - y}{x + y}$

$= \dfrac{2x - y}{x + y}$

Sum of n terms $S_n = \dfrac{n}{2}(2a + (n - 1). d)|$

$= \dfrac{n}{2}\left[2.\dfrac{x - y}{x + y} = + (n - 1). 2 - \dfrac{2x - y}{x + y}\right\}$

$$= \frac{n}{2(x+y)}\{2(x-y) + (n-1)(2x-y)\}$$

$$= \frac{n}{2(x+y)}, \{2x - 2y + 2nx - ny - 2x + y\}$$

$$= \frac{n}{2(x+y)}\{n(2x-y) - y\}$$

$$\therefore S_n = \frac{n}{2(x+y)}\{n(2x-y) - y\}$$

(viii) Given expression -26, - 24. -22, to 36 terms
        First term (a) = -26
        Common difference (d) = -24 - (-26)
                              = -24 + 26 = 2
        Sum of n terms, S_n = n/2{2a + (n - 1)d} for n = 36
        S_n = 36/2{2(-26) + (36 - 1)2}
            = 18[-52 + 70]
            = 18x18
            = 324
        ∴ S_n = 324

2. Find the sum to n terms of the A.P. 5, 2, –1, – 4, –7, ...
Solution:

Given AP is 5, 2, -1, -4, -7, ...
Here, a = 5, d = 2 - 5 = -3
We know that,
S_n = n/2{2a + (n - 1)d}
    = n/2{2.5 + (n - 1) - 3}
    = n/2{10 - 3(n - 1)}
    = n/2{13 - 3n)
∴ S_n = n/2(13 - 3n)

3. Find the sum of n terms of an A.P. whose the terms is given by a_n = 5 - 6n.
Solution:

Given nth term of the A.P as a_n = 5 - 6n
Put n = 1, we get
a_1 = 5 - 6.1 = -1
So, first term (a) = -1
Last term (a_n) = 5 - 6n = 1
Then, S_n = n/2(-1 + 5 - 6n)

= n/2(4 - 6n) = n(2 - 3n)

4. Find the sum of last ten terms of the A.P. : 8, 10, 12, 14, .. , 126
Solution:

Given A.P. 8, 10, 12, 14, .. , 126
Here, a = 8 , d = 10 – 8 = 2
We know that, $a_n = a + (n - 1)d$
So, to find the number of terms
126 = 8 + (n - 1)2
126 = 8 + 2n - 2
2n = 120
n = 60

Next, let's find the 51st term
$a_{51} = 8 + 50(2) = 108$

So, the sum of last ten terms is the sum of $a_{51} + a_{52} + a_{53} + \ldots + a_{60}$
Here, n = 10, a = 108 and l = 126
 S = 10/2 [108 + 126]
   = 5(234)
   = 1170
Hence, the sum of last ten terms of the A.P is 1170.

5. Find the sum of first 15 terms of each of the following sequences having nth term as:
(i) $a_n = 3 + 4n$
(ii) $b_n = 5 + 2n$
(iii) $x_n = 6 - n$
(iv) $y_n = 9 – 5n$
Solution:

(i)   Given an A.P. whose nth term is given by $a_n = 3 + 4n$
        To find the sum of the n terms of the given A.P., using the formula,
        $S_n = n(a + l)/ 2$
        Where, a = the first term l = the last term.
        Putting n = 1 in the given a_n, we get
        a = 3 + 4(1) = 3 + 4 = 7
        For the last term (l), here n = 15
        $a_{15} = 3 + 4(15) = 63$

        So, $S_n = 15(7 + 63)/2$
              = 15 x 35
              = 525
        Therefore, the sum of the 15 terms of the given A.P. is $S_{15} = 525$

(ii)   Given an A.P. whose nth term is given by $b_n = 5 + 2n$

To find the sum of the n terms of the given A.P., using the formula,
$S_n = n(a + l)/ 2$
Where, a = the first term l = the last term.
Putting n = 1 in the given b_n, we get
a = 5 + 2(1) = 5 + 2 = 7
For the last term (l), here n = 15
$a_{15} = 5 + 2(15) = 35$

So, $S_n = 15(7 + 35)/2$
   = 15 x 21
   = 315
Therefore, the sum of the 15 terms of the given A.P. is $S_{15} = 315$

(iii)   Given an A.P. whose n^{th} term is given by $x_n = 6 - n$
To find the sum of the n terms of the given A.P., using the formula
$S_n = n(a + l)/ 2$
Where, a = the first term l = the last term.
Putting n = 1 in the given x_n, we get
a = 6 – 1 = 5
For the last term (l), here n = 15
$a_{15} = 6 – 15 = -9$

So, $S_n = 15(5 – 9)/2$
   = 15 x (-2)
   = -30
Therefore, the sum of the 15 terms of the given A.P. is $S_{15} = -30$

(iv)   Given an A.P. whose n^{th} term is given by $y_n = 9 – 5n$
To find the sum of the n terms of the given A.P., using the formula,
$S_n = n(a + l)/ 2$
Where, a = the first term l = the last term.
Putting n = 1 in the given y_n, we get
a = 9 - 5(1) = 9 – 5 = 4
For the last term (l), here n = 15
$a_{15} = 9 - 5(15) = -66$

So, $S_n = 15(4 - 66)/2$
   = 15 x (-31)
   = -465
Therefore, the sum of the 15 terms of the given A.P. is $S_{15} = -465$

6. Find the sum of first 20 terms the sequence whose n^{th} term is $a_n = An + B$.
Solution:

Given an A.P. whose nth term is given by, $a_n = An + B$
We need to find the sum of first 20 terms.

To find the sum of the n terms of the given A.P., we use the formula,
$S_n = n(a + l)/ 2$
Where, a = the first term l = the last term,
Putting n = 1 in the given a_n, we get
a = A(1) + B = A + B
For the last term (l), here n = 20
A_{20} = A(20) + B = 20A + B
S_{20} = 20/2((A + B) + 20A + B)
= 10[21A + 2B]
= 210A + 20B
Therefore, the sum of the first 20 terms of the given A.P. is 210 A + 20B

7. Find the sum of first 25 terms of an A.P whose nth term is given by a_n = 2 - 3n.
Solution:

Given an A.P. whose nth term is given by a_n = 2 – 3n
To find the sum of the n terms of the given A.P., we use the formula,
$S_n = n(a + l)/ 2$
Where, a = the first term l = the last term.
Putting n = 1 in the given a_n, we get
a = 2 - 3(1) = -1
For the last term (l), here n = 25
a_{25} = 2 - 3(25) = -73

So, S_n = 25(-1 - 73)/2
= 25 x (-37)
= -925
Therefore, the sum of the 25 terms of the given A.P. is S_{25} = -925

8. Find the sum of first 25 terms of an A.P whose nth term is given by a_n = 7 - 3n.
Solution:

Given an A.P. whose nth term is given by a_n = 7 – 3n
To find the sum of the n terms of the given A.P., we use the formula,
$S_n = n(a + l)/ 2$
Where, a = the first term l = the last term.
Putting n = 1 in the given a_n, we get
a = 7 - 3(1) = 7 – 3 = 4
For the last term (l), here n = 25
a_{15} = 7 - 3(25) = -68

So, S_n = 25(4 - 68)/2
= 25 x (-32)
= -800
Therefore, the sum of the 15 terms of the given A.P. is S_{25} = -800

9. If the sum of a certain number of terms starting from first term of an A.P. is 25, 22, 19, . . ., is 116. Find the last term.

Solution:

Given the sum of the certain number of terms of an A.P. = 116

We know that, $S_n = n/2[2a + (n − 1)d]$

Where;   a = first term for the given A.P.

                d = common difference of the given A.P.

                n = number of terms So for the given A.P.(25, 22, 19,...)

Here we have, the first term (a) = 25

The sum of n terms $S_n = 116$

Common difference of the A.P. (d) = a_2 - a_1 = 22 – 25 = -3

Now, substituting values in S_n

$\Rightarrow 116 = n/2[2(25) + (n − 1)(−3)]$

$\Rightarrow (n/2)[50 + (−3n + 3)] = 116$

$\Rightarrow (n/2)[53 − 3n] = 116$

$\Rightarrow 53n - 3n^2 = 116 \times 2$

Thus, we get the following quadratic equation,

$3n^2 - 53n + 232 = 0$

By factorization method of solving, we have

$\Rightarrow 3n^2 - 24n - 29n + 232 = 0$

$\Rightarrow 3n(n - 8) - 29 (n - 8) = 0$

$\Rightarrow (3n - 29)(n - 8) = 0$

So, 3n - 29 = 0

$\Rightarrow n = 29/3$

Also, n - 8 = 0

$\Rightarrow n = 8$

Since, n cannot be a fraction, so the number of terms is taken as 8.

So, the term is:

$a_8 = a_1 + 7d = 25 + 7(-3) = 25 - 21 = 4$

Hence, the last term of the given A.P. such that the sum of the terms is 116 is 4.

10. (i) How many terms of the sequence 18, 16, 14.... should be taken so that their sum is zero.
    (ii) How many terms are there in the A.P. whose first and fifth terms are -14 and 2 respectively and the sum of the terms is 40?
    (iii) How many terms of the A.P. 9, 17, 25, . . . must be taken so that their sum is 636?
    (iv) How many terms of the A.P. 63, 60, 57, . . . must be taken so that their sum is 693?
    (v) How many terms of the A.P. is 27, 24, 21. . . should be taken that their sum is zero?

Solution:

(i)   Given AP. is 18, 16, 14, ...

         We know that,

         $S_n = n/2[2a + (n − 1)d]$

         Here,

         The first term (a) = 18

         The sum of n terms (S_n) = 0 (given)

Common difference of the A.P.
(d) = a_2 - a_1 = 16 - 18 = – 2
So, on substituting the values in S_n
$\Rightarrow$ 0 = n/2[2(18) + (n − 1)(−2)]
$\Rightarrow$ 0 = n/2[36 + (−2n + 2)]
$\Rightarrow$ 0 = n/2[38 − 2n] Further, n/2
$\Rightarrow$ n = 0 Or, 38 - 2n = 0
$\Rightarrow$ 2n = 38
$\Rightarrow$ n = 19
Since, the number of terms cannot be zer0, hence the number of terms (n) should be 19.

(ii)   Given, the first term (a) = -14, Filth term (a_5) = 2, Sum of terms (S_n) = 40 of the A.P.
If the common difference is taken as d.
Then, a_5 = a + 4d
$\Rightarrow$ 2 = -14 + 4d
$\Rightarrow$ 2 + 14 = 4d
$\Rightarrow$ 4d = 16
$\Rightarrow$ d = 4

Next, we know that S_n = n/2[2a + (n − 1)d]
Where; a = first term for the given A.P.
        d = common difference of the given A.P.
        n = number of terms

Now, on substituting the values in S_n
$\Rightarrow$ 40 = n/2[2(−14) + (n − 1)(4)]
$\Rightarrow$ 40 = n/2[−28 + (4n − 4)]
$\Rightarrow$ 40 = n/2[−32 + 4n]
$\Rightarrow$ 40(2) = - 32n + 4n^2
So, we get the following quadratic equation,
4n^2 - 32n - 80 = 0
$\Rightarrow$ n^2 - 8n - 20 = 0
On solving by factorization method, we get
n^2 - 10n + 2n - 20 = 0
$\Rightarrow$ n(n - 10) + 2(n - 10) = 0
$\Rightarrow$ (n + 2)(n - 10) = 0
Either, n + 2 = 0
$\Rightarrow$ n = -2
Or, n - 10 = 0
$\Rightarrow$ n = 10
Since the number of terms cannot be negative.
Therefore, the number of terms (n) is 10.

(iii)   Given AP is 9, 17, 25,...
We know that,
S_n = n/2[2a + (n − 1)d]

Here we have,

The first term (a) = 9 and the sum of n terms (S_n) = 636

Common difference of the A.P. (d) = a_2 - a_1 = 17 - 9 = 8

Substituting the values in S_n, we get

$\Longrightarrow$ 636 = n/2[2(9) + (n − 1)(8)]

$\Longrightarrow$ 636 = n/2[18 + (8n − 8)]

$\Longrightarrow$ 636(2) = (n)[10 + 8n]

$\Longrightarrow$ 1271 = 10n + 8n^2

Now, we get the following quadratic equation,

$\Longrightarrow$ 8n^2 + 10n - 1272 = 0

$\Longrightarrow$ 4n^2+ 5n - 636 = 0

On solving by factorisation method, we have

$\Longrightarrow$ 4n^2 - 48n + 53n - 636 = 0

$\Longrightarrow$ 4n(n - 12) + 53(n - 12) = 0

$\Longrightarrow$ (4n + 53)(n - 12) = 0

Either 4n + 53 = 0 $\Longrightarrow$ n = -53/4

Or, n - 12 = 0 $\Longrightarrow$ n = 12

Since, the number of terms cannot be a fraction.

Therefore, the number of terms (n) is 12.

(iv)   Given A.P. is 63, 60, 57,...

We know that,

S_n = n/2[2a + (n − 1)d]

Here we have,

the first term (a) = 63

The sum of n terms (S_n) = 693

Common difference of the A.P. (d) = a_2 - a_1 = 60 - 63 = –3

On substituting the values in S_n we get

$\Longrightarrow$ 693 = n/2[2(63) + (n − 1)(−3)]

$\Longrightarrow$ 693 = n/2[126+(−3n + 3)]

$\Longrightarrow$ 693 = n/2[129 − 3n]

$\Longrightarrow$ 693(2) = 129n - 3n^2

Now, we get the following quadratic equation.

$\Longrightarrow$ 3n^2 - 129n + 1386 = 0

$\Longrightarrow$ n^2 - 43n + 462

Solving by factorisation method, we have

$\Longrightarrow$ n^2 - 22n - 21n + 462 = 0

$\Longrightarrow$ n(n - 22) -21(n - 22) = 0

$\Longrightarrow$ (n - 22) (n - 21) = 0

Either, n - 22 = 0 $\Longrightarrow$ n = 22

Or, n - 21 = 0 $\Longrightarrow$ n = 21

Now, the 22nd term will be a_{22} = a_1 + 21d = 63 + 21(-3) = 63 - 63 = 0

So, the sum of 22 as well as 21 terms is 693.

Therefore, the number of terms (n) is 21 or 22.

(v)   Given A.P. is 27, 24, 21. . .
        We know that,
        $S_n = n/2[2a + (n − 1)d]$
        Here we have, the first term (a) = 27
        The sum of n terms (S_n) = 0
        Common difference of the A.P. (d) = $a_2 - a_1$ = 24 - 27 = -3
        On substituting the values in S_n, we get
        $\Rightarrow$ 0 = n/2[2(27) + (n − 1)(− 3)]
        $\Rightarrow$ 0 = (n)[54 + (n - 1)(-3)]
        $\Rightarrow$ 0 = (n)[54 - 3n + 3]
        $\Rightarrow$ 0 = n [57 - 3n] Further we have, n = 0 Or, 57 - 3n = 0
        $\Rightarrow$ 3n = 57
        $\Rightarrow$ n = 19
        The number of terms cannot be zero,
        Hence, the numbers of terms (n) is 19.

11. Find the sum of the first
(i) 11 terms of the A.P. : 2, 6, 10, 14, . . .
(ii) 13 terms of the A.P. : -6, 0, 6, 12, . . .
(iii) 51 terms of the A.P. : whose second term is 2 and fourth term is 8.
Solution:

We know that the sum of terms for different arithmetic progressions is given by
$S_n = n/2[2a + (n − 1)d]$
Where; a = first term for the given A.P. d = common difference of the given A.P. n = number of terms

(i)   Given A.P 2, 6, 10, 14,... to 11 terms.
        Common difference (d) = $a_2 - a_1$ = 10 - 6 = 4
        Number of terms (n) = 11
        First term for the given A.P. (a) = 2
        So,
        S_{11} = 11/2[2(2) + (11 − 1)4]
                = 11/2[2(2) + (10)4]
                = 11/2[4 + 40]
                = 11 × 22
                = 242
        Hence, the sum of first 11 terms for the given A.P. is 242

(ii)   Given A.P. – 6, 0, 6, 12, ... to 13 terms.
        Common difference (d) = $a_2 - a_1$ = 6 - 0 = 6
        Number of terms (n) = 13
        First term (a) = -6
        So,
        S_{13} = 13/2[2(− 6) + (13 −1)6]
                = 13/2[(−12) + (12)6]
                = 13/2[60] = 390

Hence, the sum of first 13 terms for the given A.P. is 390

(iii)   51 terms of an AP whose $a_2 = 2$ and $a_4 = 8$
We know that, $a_2 = a + d$
$2 = a + d$ ...(2)
Also, $a_4 = a + 3d$
$8 = a + 3d$ ... (2)
Subtracting (1) from (2), we have
$2d = 6$
$d = 3$
Substituting $d = 3$ in (1), we get
$2 = a + 3$
$\implies a = -1$

Given that the number of terms (n) = 51
First term (a) = -1
So,
S_n $= 51/2[2(-1) + (51 - 1)(3)]$
            $= 51/2[-2 + 150]$
            $= 51/2[148]$
            $= 3774$
Hence, the sum of first 51 terms for the A.P. is 3774.

12. Find the sum of
(i) the first 15 multiples of 8
(ii) the first 40 positive integers divisible by (a) 3 (b) 5 (c) 6.
(iii) all 3 - digit natural numbers which are divisible by 13.
(iv) all 3 - digit natural numbers which are multiples of 11.

Solution:
We know that the sum of terms for an A.P is given by
$S_n = n/2[2a + (n - 1)d]$
Where; a = first term for the given A.P. d = common difference of the given A.P. n = number of terms

(i)   Given, first 15 multiples of 8.
These multiples form an A.P: 8, 16, 24, …… , 120
Here, a = 8 , d = 61 – 8 = 8 and the number of terms(n) = 15
Now, finding the sum of 15 terms, we have

$$S_n = \frac{15}{2}[2(8) + (15 - 1)8]$$

$$= \frac{15}{2}[16 + (14)8]$$

$$= \frac{15}{2}[16 + 12]$$

$$= \frac{15}{2}[128]$$

$$= 960 \qquad\qquad \backslash$$

Hence, the sum of the first 15 multiples of 8 is 960

(ii)(a) First 40 positive integers divisible by 3.
Hence, the first multiple is 3 and the 40th multiple is 120.
And, these terms will form an A.P. with the common difference of 3.
Here, First term (a) = 3
Number of terms (n) = 40
Common difference (d) = 3
So, the sum of 40 terms
S_{40} = 40/2[2(3) + (40 − 1)3]
       = 20[6 + (39)3]
       = 20(6 + 117)
       = 20(123) = 2460
Thus, the sum of first 40 multiples of 3 is 2460.

(b)   First 40 positive integers divisible by 5
Hence, the first multiple is 5 and the 40th multiple is 200.
And, these terms will form an A.P. with the common difference of 5.
Here, First term (a) = 5
Number of terms (n) = 40
Common difference (d) = 5
So, the sum of 40 terms
S_{40} = 40/2[2(5) + (40 − 1)5]
       = 20[10 + (39)5]
       = 20 (10 + 195)
       = 20 (205) = 4100
Hence, the sum of first 40 multiples of 5 is 4100.

(c)   First 40 positive integers divisible by 6

Hence, the first multiple is 6 and the 40th multiple is 240.
And, these terms will form an A.P. with the common difference of 6.
Here, First term (a) = 6
Number of terms (n) = 40
Common difference (d) = 6
So, the sum of 40 terms
S_{40} = 40/2[2(6) + (40 − 1)6]
        = 20[12 + (39)6]
        =20(12 + 234)
        = 20(246) = 4920
Hence, the sum of first 40 multiples of 6 is 4920.

(iii)   All 3 digit natural number which are divisible by 13.
    So, we know that the first 3 digit multiple of 13 is 104 and the last 3 digit multiple of 13 is 988.
    And, these terms form an A.P. with the common difference of 13.
    Here, first term (a) = 104 and the last term (l) = 988
    Common difference (d) = 13
    Finding the number of terms in the A.P. by, a_n = a + (n − 1)d
    We have,
    988 = 104 + (n - 1)13
    ⟹ 988 = 104 + 13n -13
    ⟹ 988 = 91 + 13n
    ⟹ 13n = 897
    ⟹ n = 69
    Now, using the formula for the sum of n terms, we get
    S_{69} = 69/2[2(104) + (69 − 1)13]
         = 69/2[208 + 884]
         = 69/2[1092]
         = 69(546)
         = 37674
    Hence, the sum of all 3 digit multiples of 13 is 37674.

(iv)   All 3 digit natural number which are multiples of 11.
    So, we know that the first 3 digit multiple of 11 is 110 and the last 3 digit multiple of 13 is 990.
    And, these terms form an A.P. with the common difference of 11.
    Here, first term (a) = 110 and the last term (l) = 990
    Common difference (d) = 11
    Finding the number of terms in the A.P. by, a_n = a + (n − 1)d
    We get,
    990 = 110 + (n - 1)11
    ⟹ 990 = 110 + 11n -11
    ⟹ 990 = 99 + 11n
    ⟹ 11n = 891
    ⟹ n = 81
    Now, using the formula for the sum of n terms, we get
    S_{81} = 81/2[2(110) + (81 − 1)11]

= 81/2[220 + 880]
= 81/2[1100]
= 81(550)
= 44550
Hence, the sum of all 3 digit multiples of 11 is 44550.

13. Find the sum:
(i) 2 + 4 + 6 + . . . + 200
(ii) 3 + 11 + 19 + . . . + 803
(iii) (-5) + (-8) + (-11) + . . . + (- 230)
(iv) 1 + 3 + 5 + 7 + . . . + 199

$$(v)\ 7 + 10\frac{1}{2} + 14 + \cdots + 84$$

(vi) 34 + 32 + 30 + . . . + 10
(vii) 25 + 28 + 31 + . . . + 100
Solution:

We know that the sum of terms for an A.P is given by
S_n = n/2[2a + (n − 1)d]
Where; a = first term for the given A.P. d = common difference of the given A.P. n = number of terms
Or S_n = n/2[a + l]
Where; a = first term for the given A.P. ;l = last term for the given A.P

(i)   Given series. 2 + 4 + 6 + . . . + 200 which is an A.P
        Where, a = 2 ,d = 4 – 2 = 2 and last term (a_n = l) = 200
        We know that, a_n = a + (n - 1)d
        So,
        200 = 2 + (n - 1)2
        200 = 2 + 2n – 2
        n = 200/2 = 100

        Now, for the sum of these 100 terms
        S_{100} = 100/2 [2 + 200]
                = 50(202)
                = 10100
        Hence, the sum of terms of the given series is 10100.

(ii)   Given series. 3 + 11 + 19 + . . . + 803 which is an A.P
        Where, a = 3 ,d = 11 – 3 = 8 and last term (a_n = l) = 803
        We know that, a_n = a + (n - 1)d
        So,
        803 = 3 + (n - 1)8
        803 = 3 + 8n – 8
        n = 808/8 = 101

Now, for the sum of these 101 terms
S_{101} = 101/2 [3 + 803]
            = 101(806)/2
            = 101 x 403
            = 40703
Hence, the sum of terms of the given series is 40703.

(iii)   Given series (-5) + (-8) + (-11) + . . . + (- 230) which is an A.P
        Where, a = -5 ,d = -8 – (-5) = -3 and last term (a_n = l) = -230
        We know that, a_n = a + (n - 1)d
        So,
        -230 = -5 + (n - 1)(-3)
        -230 = -5 - 3n + 3
        3n = -2 + 230
        n = 228/3 = 76

        Now, for the sum of these 76 terms
        S_{76} = 76/2 [-5 + (-230)]
                   = 38 x (-235)
                   = -8930
        Hence, the sum of terms of the given series is -8930.

(iv)   Given series. 1 + 3 + 5 + 7 + . . . + 199 which is an A.P
        Where, a = 1 ,d = 3 – 1 = 2 and last term (a_n = l) = 199
        We know that, a_n = a + (n - 1)d
        So,
        199 = 1 + (n - 1)2
        199 = 1 + 2n – 2
        n = 200/2 = 100

        Now, for the sum of these 100 terms
        S_{100} = 100/2 [1 + 199]
                    = 50(200)
                    = 10000
        Hence, the sum of terms of the given series is 10000.

(v)   Given series $7 + 10\dfrac{1}{2} + 14 + \cdots + 84$ which is an A.P

        Where, a = 7, d = 10 ½ - 7 = (21 – 14)/2 = 7/2 and last term (a_n = l) = 84
        We know that, a_n = a + (n - 1)d
        So,
        84 = 7 + (n - 1)(7/2)
        168 = 14 + 7n – 7
        n = (168 – 7)/7 = 161/7 = 23

Now, for the sum of these 23 terms
S_{23} = 23/2 [7 + 84]
= 23(91)/2
= 2093/2
Hence, the sum of terms of the given series is 2093/2.

(vi)   Given series, 34 + 32 + 30 + . . . + 10 which is an A.P
Where, a = 34 ,d = 32 – 34 = -2 and last term (a_n = l) = 10
We know that, a_n = a + (n - 1)d
So,
10 = 34 + (n - 1)(-2)
10 = 34 - 2n + 2
n = (36 – 10)/2 = 13

Now, for the sum of these 13 terms
S_{13} = 13/2 [34 + 10]
= 13(44)/2
= 13 x 22
= 286
Hence, the sum of terms of the given series is 286.

(vii)   Given series, 25 + 28 + 31 + . . . + 100 which is an A.P
Where, a = 25 ,d = 28 – 25 = 3 and last term (a_n = l) = 100
We know that, a_n = a + (n - 1)d
So,
100 = 25 + (n - 1)(3)
100 = 25 + 3n - 3
n = (100 – 22)/3 = 26

Now, for the sum of these 26 terms
S_{100} = 26/2 [25 + 100]
= 13(124)
= 1625
Hence, the sum of terms of the given series is 1625.

**14. The first and the last terms of an A.P. are 17 and 350 respectively. If the common difference is
9, how many terms are there and what is their sum?**
Solution:

Given, the first term of the A.P (a) = 17
The last term of the A.P (l) = 350
The common difference (d) of the A.P. = 9
Let the number of terms be n. And, we know that; l = a + (n - 1)d
So, 350 = 17 + (n- 1) 9
⟹ 350 = 17 + 9n - 9
⟹ 350 = 8 + 9n

$\Longrightarrow$ 350 - 8 = 9n

Thus we get, n = 38

Now, finding the sum of terms

S_n = n/2[a + l]

          = 38/2(17 + 350)

          = 19 × 367

          = 6973

Hence, the number of terms is of the A.P is 38 and their sum is 6973.

15. The third term of an A.P. is 7 and the seventh term exceeds three times the third term by 2. Find the first term, the common difference and the sum of first 20 terms.
Solution:

Let's consider the first term as a and the common difference as d.

Given,

a_3 = 7 .... (1) and,

a_7 = 3a_3 + 2   .... (2)

So, using (1) in (2), we get,

a_7 = 3(7) + 2 = 21 + 2 = 23 .... (3)

Also, we know that

a_n = a +(n - 1)d

So, the 3th term (for n = 3),

a_3 = a + (3 - 1)d

$\Longrightarrow$ 7 = a + 2d   (Using 1)

$\Longrightarrow$ a = 7 - 2d   .... (4)

Similarly, for the 7th term (n = 7),

a_7 = a + (7 - 1) d 24 = a + 6d = 23 (Using 3)

a = 23 - 6d .... (5)

Subtracting (4) from (5), we get,

a - a = (23 - 6d) - (7 - 2d)

$\Longrightarrow$ 0 = 23 - 6d - 7 + 2d

$\Longrightarrow$ 0 = 16 - 4d

$\Longrightarrow$ 4d = 16

$\Longrightarrow$ d = 4

Now, to find a, we substitute the value of d in (4), a = 7 - 2(4)

$\Longrightarrow$ a = 7 - 8

a = -1

Hence, for the A.P. a = -1 and d = 4

For finding the sum, we know that

S_n = n/2[2a + (n − 1)d] and n = 20 (given)

S_{20} = 20/2[2(−1) + (20 − 1)(4)]

          = (10)[-2 + (19)(4)]

          = (10)[-2 + 76]

          = (10)[74]

          = 740

Hence, the sum of first 20 terms for the given A.P. is 740

16. The first term of an A.P. is 2 and the last term is 50. The sum of all these terms is 442. Find the common difference.
Solution:

Given,
The first term of the A.P (a) = 2
The last term of the A.P (l) = 50
Sum of all the terms S_n = 442
So, let the common difference of the A.P. be taken as d.
The sum of all the terms is given as,
442 = (n/2)(2 + 50)
$\Longrightarrow$ 442 = (n/2)(52)
$\Longrightarrow$ 26n = 442
$\Longrightarrow$ n = 17
Now, the last term is expressed as
50 = 2 + (17 - 1)d
$\Longrightarrow$ 50 = 2 + 16d
$\Longrightarrow$ 16d = 48
$\Longrightarrow$ d = 3
Thus, the common difference of the A.P. is d = 3.

17. If 12ᵗʰ term of an A.P. is -13 and the sum of the first four terms is 24, what is the sum of first 10 terms?
Solution:

Let us take the first term as a and the common difference as d.
Given,
a_{12} = -13 S_4 = 24
Also, we know that a_n = a + (n - 1)d
So, for the 12th term
a_{12} = a + (12 - 1)d = -13
$\Longrightarrow$ a + 11d = -13
a = -13 - 11d .... (1)
And, we that for sum of terms
S_n = n/2[2a + (n − 1)d]
Here, n = 4
S_4 = 4/2[2(a) + (4 − 1)d]
$\Longrightarrow$ 24 = (2)[2a + (3)(d)]
$\Longrightarrow$ 24 = 4a + 6d
$\Longrightarrow$ 4a = 24 - 6d

$$\Longrightarrow a = 6 - \frac{6}{4}d \ \dots (2)$$

Subtracting (1) from (2), we have

$$\Rightarrow a - a = \left(6 - \frac{6}{4}d\right) - (-13 - 11d)$$

$$\Rightarrow 0 = 6 - \frac{6}{4}d + 13d + 11d$$

$$\Rightarrow 0 = 19 + \frac{44d - 6d}{4s}$$

Further simplifying for d, we get,

$$\Rightarrow 0 = 19 + \frac{38}{4}d$$

$$\Rightarrow -19 = \frac{19}{2}d$$

$\Rightarrow$ -19 × 2 = 19d
$\Rightarrow$ d = – 2
On substituting the value of d in (1), we find a
a = -13 - 11(-2)
a = -13 + 22
a = 9
Next, the sum of 10 term is given by
S_{10} = 10/2[2(9) + (10 − 1)(−2)]
       = (5)[19 + (9)(-2)]
       = (5)(18 - 18) = 0
Thus, the sum of first 10 terms for the given A.P. is S_{10} = 0.

18. Find the sum of n terms of the series (4 - (1/n)) + (4 - (2/n)) + (4 - (3/n)) + ...
Solution:

Let the first term be taken as a.
Given,
a = 4 - 1/n
So, common difference is
d = (4 - (2/n)) - (4 - (1/n))
  = (4n - 2 - 4n + 1)/n
  = -1/n
By using the formula,
S_n = n/2[2a + (n − 1)d]
We get,
  = n/2[2(4−(1/n)) + (n − 1)(-1/n)]
  = n/2[8 - (2/n) + (-1 + (1/n))]

= n/2[(8n - 2 - n + 1)/n]
= 1/2(7n - 1)

Hence, the sum of n terms of the series is 1/2(7n - 1).

19. In an A.P., if the first term is 22, the common difference is – 4 and the sum to n terms is 64, find n.
Solution:

Given that,
a = 22, d = – 4 and S_n = 64
Let us consider the number of terms as n.
For sum of terms in an A.P, we know that
S_n = n/2[2a + (n − 1)d]
Where; a = first term for the given A.P. d = common difference of the given A.P. n = number of terms

So,
$\Rightarrow S_n$ = n/2[2(22) + (n − 1)(−4)]
$\Rightarrow$ 64 = n/2[2(22) + (n − 1)(−4)]
$\Rightarrow$ 64(2) = n(48 - 4n)
$\Rightarrow$ 128 = 48n - 4n^2
After rearranging the terms, we have a quadratic equation
4n^2 - 48n + 128 = 0,
n^2 - 12n + 32 = 0   [dividing by 4 on both sides]
n^2 - 12n + 32 = 0
Solving by factorisation method,
n^2 - 8n - 4n + 32 = 0
n (n - 8) - 4 (n - 8) = 0
(n - 8) (n - 4) = 0
So, we get n - 8 = 0 $\Rightarrow$ n = 8
Or, n - 4 = 0 $\Rightarrow$ n = 4
Hence, the number of terms can be either n = 4 or 8.

20. In an A.P., if the 5th and 12th terms are 30 and 65 respectively, what is the sum of first 20 terms?
Solution:

Let's take the first term as a and the common difference to be d
Given that,
a_5 = 30 and a_{12} = 65
And, we know that a_n = a + (n - 1)d
So,
a_5 = a + (5 - 1)d
30 = a + 4d
a = 30 - 4d   .... (i)

Similarly, $a_{12} = a + (12 - 1)$ d
$65 = a + 11d$
$a = 65 - 11d$ .... (ii)

Subtracting (i) from (ii), we have
$a - a = (65 - 11d) - (30 - 4d)$
$0 = 65 - 11d - 30 + 4d$
$0 = 35 - 7d$
$7d = 35$
$d = 5$
Putting d in (i), we get
$a = 30 - 4(5)$
$a = 30 - 20$
$a = 10$
Thus for the A.P; $d = 5$ and $a = 10$
Next, to find the sum of first 20 terms of this A.P., we use the following formula for the sum of n
terms of an A.P.,
$S_n = n/2[2a + (n − 1)d]$
Where;
a = first term of the given A.P.
d = common difference of the given A.P.
n = number of terms
Here n = 20, so we have
S_{20} $= 20/2[2(10) + (20 − 1)(5)]$
       $= (10)[20 + (19)(5)]$
       $= (10)[20 + 95]$
       $= (10)[115]$
       $= 1150$
Hence, the sum of first 20 terms for the given A.P. is 1150

**21. Find the sum of first 51 terms of an A.P. whose second and third terms are 14 and 18
respectively.**
Solution:

Let's take the first term as a and the common difference as d.
Given that,
$a_2 = 14$ and $a_3 = 18$
And, we know that $a_n = a + (n - 1)d$
So,
 $a_2 = a + (2 - 1)d$
$\implies 14 = a + d$
$\implies a = 14 - d$ .... (i)
Similarly,
$a_3 = a + (3 - 1)d$
$\implies 18 = a + 2d$
$\implies a = 18 - 2d$ .... (ii)

Subtracting (i) from (ii), we have
a - a = (18 - 2d) - (14 - d)
0 = 18 - 2d - 14 + d
0 = 4 - d
d = 4
Putting d in (i), to find a
a = 14 - 4
a = 10
Thus, for the A.P. d = 4 and a = 10
Now, to find sum of terms
S_n = n/2(2a + (n − 1)d)
Where,
a = the first term of the A.P.
d = common difference of the A.P.
n = number of terms So, using the formula for
n = 51,
⟹ S_{51} = 51/2[2(10) + (51 - 1)(4)]
        = 51/2[20 + (40)4]
        = 51/2[220]
        = 51(110)
        = 5610
Hence, the sum of the first 51 terms of the given A.P. is 5610

22. If the sum of 7 terms of an A.P. is 49 and that of 17 terms is 289, find the sum of n terms.
Solution:

Given,
Sum of 7 terms of an A.P. is 49
⟹ S_7 = 49
And, sum of 17 terms of an A.P. is 289
⟹ S_{17} = 289
Let the first term of the A.P be a and common difference as d.
And, we know that the sum of n terms of an A.P is
S_n = n/2[2a + (n − 1)d]
So,
S_7 = 49 = 7/2[2a + (7 - 1)d]
        = 7/2 [2a + 6d]
        = 7[a + 3d]
⟹ 7a + 21d = 49
a + 3d = 7 ….. (i)

Similarly,
S_{17} = 17/2[2a + (17 - 1)d]
        = 17/2 [2a + 16d]
        = 17[a + 8d]
⟹ 17[a + 8d] = 289

a + 8d = 17 ….. (ii)
Now, subtracting (i) from (ii), we have
a + 8d – (a + 3d) = 17 – 7
5d = 10
d = 2

Putting d in (i), we find a
a + 3(2) = 7
a = 7 – 6 = 1
So, for the A.P: a = 1 and d = 2

For the sum of n terms is given by,
S_n = n/2[2(1) + (n − 1)(2)]
         = n/2[2 + 2n - 2]
         = n/2[2n]
         = n^2
Therefore, the sum of n terms of the A.P is given by n^2.

23. The first term of an A.P. is 5, the last term is 45 and the sum is 400. Find the number of terms and the common difference.
Solution:

Sum of first n terms of an A.P is given by S_n = n/2(2a + (n − 1)d)
Given,
First term (a) = 5, last term (a_n) = 45 and sum of n terms (S_n) = 400
Now, we know that
a_n = a + (n - 1)d
$\implies$ 45 = 5 + (n - 1)d
$\implies$ 40 = nd - d
$\implies$ nd - d = 40 .... (1)
Also,
S_n = n/2(2(a) + (n − 1)d)
400 = n/2(2(5) + (n − 1)d)
800 = n (10 + nd - d)
800 = n (10 + 40)   [using (1)]
$\implies$ n = 16

Putting n in (1), we find d
nd - d = 40
16d - d = 40
15d = 40
d = 8/3
Therefore, the common difference of the given A.P. is 8/3.

24. In an A.P. the first term is 8, n^{th} term is 33 and the sum of first n term is 123. Find n and the d, the common difference.

Solution:

Given,
The first term of the A.P (a) = 8
The nth term of the A.P (l) = 33
And, the sum of all the terms S_n = 123
Let the common difference of the A.P. be d.
So, find the number of terms by
      123 = (n/2)(8 + 33)
      123 = (n/2)(41)
      n = (123 x 2)/ 41
      n = 246/41
      n = 6
Next, to find the common difference of the A.P. we know that
      l = a + (n - 1)d
      33 = 8 + (6 - 1)d
      33 = 8 + 5d
      5d = 25
      d = 5
Thus, the number of terms is n = 6 and the common difference of the A.P. is d = 5.

25. In an A.P. the first term is 22, n[th] term is -11 and the sum of first n term is 66. Find n and the d, the common difference.
Solution:

Given,
The first term of the A.P (a) = 22
The nth term of the A.P (l) = -11
And, sum of all the terms S_n = 66
Let the common difference of the A.P. be d.
So, finding the number of terms by
66 = (n/2)[22 + (−11)]
66 = (n/2)[22 − 11]
(66)(2) = n(11)
6 × 2 = n
n = 12
Now, for finding d
We know that, l = a + (n - 1)d
- 11 = 22 + (12 - 1)d
-11 = 22 + 11d
11d = − 33
d = − 3
Hence, the number of terms is n = 12 and the common difference d = -3

26. The first and the last terms of an A.P. are 7 and 49 respectively. If sum of all its terms is 420, find the common difference.

Solution:

Given,
First term (a) = 7, last term (a_n) = 49 and sum of n terms (S_n) = 420
Now, we know that
$a_n = a + (n - 1)d$
$\implies 49 = 7 + (n - 1)d$
$\implies 43 = nd - d$
$\implies nd - d = 42$ ..... (1)
Next,
$S_n = n/2(2(7) + (n - 1)d)$
$\implies 840 = n[14 + nd - d]$
$\implies 840 = n[14 + 42]$ [using (1)]
$\implies 840 = 54n$
$\implies n = 15$ .... (2)
So, by substituting (2) in (1), we have
$nd - d = 42$
$\implies 15d - d = 42$
$\implies 14d = 42$
$\implies d = 3$
Therefore, the common difference of the given A.P. is 3.

**27. The first and the last terms of an A.P are 5 and 45 respectively. If the sum of all its terms is
400, find its common difference.**
Solution:

Given,
First term (a) = 5 and the last term (l) = 45
Also, $S_n = 400$
We know that,
$a_n = a + (n - 1)d$
$\implies 45 = 5 + (n - 1)d$
$\implies 40 = nd - d$
$\implies nd - d = 40$ ..... (1)
Next,
$S_n = n/2(2(5) + (n - 1)d)$
$\implies 400 = n[10 + nd - d]$
$\implies 800 = n[10 + 40]$ [using (1)]
$\implies 800 = 50n$
$\implies n = 16$ .... (2)
So, by substituting (2) in (1), we have
$nd - d = 40$
$\implies 16d - d = 40$
$\implies 15d = 40$
$\implies d = 8/3$

Therefore, the common difference of the given A.P. is 8/3.

**28. The sum of first q terms of an A.P. is 162. The ratio of its 6th term to its 13th term is 1: 2. Find
the first and 15th term of the A.P.**
Solution:

Let a be the first term and d be the common difference.
And we know that, sum of first n terms is:
$S_n = n/2(2a + (n − 1)d)$
Also, nth term is given by $a_n = a + (n - 1)d$

From the question, we have
$S_q = 162$ and $a_6 : a_{13} = 1 : 2$
So,
$2a_6 = a_{13}$
$\Rightarrow 2 [a + (6 - 1d)] = a + (13 - 1)d$
$\Rightarrow 2a + 10d = a + 12d$
$\Rightarrow a = 2d$ .... (1)
And, $S_9 = 162$
$\Rightarrow S_9 = 9/2(2a + (9 − 1)d)$
$\Rightarrow 162 = 9/2(2a + 8d)$
$\Rightarrow 162 × 2 = 9[4d + 8d]$ [from (1)]
$\Rightarrow 324 = 9 × 12d$
$\Rightarrow d = 3$
$\Rightarrow a = 2(3)$ [from (1)]
$\Rightarrow a = 6$
Hence, the first term of the A.P. is 6
For the 15th term, $a_{15} = a + 14d = 6 + 14 × 3 = 6 + 42$
Therefore, $a_{15} = 48$

29. If the 10th term of an A.P. is 21 and the sum of its first 10 terms is 120, find its nth term.
Solution:

Let's consider a to be the first term and d be the common difference.
And we know that, sum of first n terms is:
$S_n = n/2(2a + (n − 1)d)$ and nth term is given by: $a_n = a + (n - 1)d$

Now, from the question we have
$S_{10} = 120$
$\Rightarrow 120 = 10/2(2a + (10 − 1)d)$
$\Rightarrow 120 = 5(2a + 9d)$
$\Rightarrow 24 = 2a + 9d$ .... (1)
Also given that, $a_{10} = 21$
$\Rightarrow 21 = a + (10 - 1)d$
$\Rightarrow 21 = a + 9d$ .... (2)
Subtracting (2) from (1), we get

24 - 21 = 2a + 9d - a - 9d
$\Rightarrow$ a = 3
Now, on putting a = 3 in equation (2), we get
   3 + 9d = 21
   9d = 18
   d = 2
Thus, we have the first term(a) = 3 and the common difference(d) = 2
Therefore, the nth term is given by
a_n = a + (n - 1)d = 3 + (n - 1)2
         = 3 + 2n -2
         = 2n + 1
Hence, the nth term of the A.P is (a_n) = 2n + 1.

30. The sum of first 7 terms of an A.P. is 63 and the sum of its next 7 terms is 161. Find the 28th term of this A.P.
Solution:

Let's take a to be the first term and d to be the common difference.
And we know that, sum of first n terms
S_n = n/2(2a + (n − 1)d)
Given that sum of the first 7 terms of an A.P. is 63.
S_7 = 63
And sum of next 7 terms is 161.
So, the sum of first 14 terms = Sum of first 7 terms + sum of next 7 terms
S_{14} = 63 + 161 = 224
Now, having
S_7 = 7/2(2a + (7 − 1)d)
$\Rightarrow$ 63(2) = 7(2a + 6d)
$\Rightarrow$ 9 × 2 = 2a + 6d
$\Rightarrow$ 2a + 6d = 18 . . . . (1)
And,
S_{14} = 14/2(2a + (14 − 1)d)
$\Rightarrow$ 224 = 7(2a + 13d)
$\Rightarrow$ 32 = 2a + 13d .... (2)
Now, subtracting (1) from (2), we get
$\Rightarrow$ 13d - 6d = 32 - 18
$\Rightarrow$ 7d = 14
$\Rightarrow$ d = 2
Using d in (1), we have
2a + 6(2) = 18
2a = 18 - 12
a = 3
Thus, from n^{th} term
$\Rightarrow$ a_{28} = a + (28 - 1)d
          = 3 + 27 (2)
          = 3 + 54 = 57

Therefore, the 28th term is 57.

31. The sum of first seven terms of an A.P. is 182. If its 4th and 17th terms are in ratio 1: 5, find the A.P.
Solution:

Given that,
S_{17} = 182
And, we know that the sum of first n term is:
S_n = n/2(2a + (n − 1)d)
So,
S_7 = 7/2(2a + (7 − 1)d)
182 × 2 = 7(2a + 6d)
364 = 14a + 42d
26 = a + 3d
a = 26 - 3d ... (1)
Also, it's given that 4th term and 17th term are in a ratio of 1: 5. So, we have
⟹ 5(a_4) = 1(a_{17})
⟹ 5 (a + 3d) = 1 (a + 16d)
⟹ 5a + 15d = a + 16d
⟹ 4a = d .... (2)
Now, substituting (2) in (1), we get
⟹ 4 (26 - 3d) = d
⟹ 104 - 12d = d
⟹ 104 = 13d
⟹ d = 8
Putting d in (2), we get
⟹ 4a = d
⟹ 4a = 8
⟹ a = 2
Therefore, the first term is 2 and the common difference is 8. So, the A.P. is 2, 10, 18, 26, . ..

32. The nth term of an A.P is given by (-4n + 15). Find the sum of first 20 terms of this A.P.
Solution:

Given,
The nth term of the A.P = (-4n + 15)
So, by putting n = 1 and n = 20 we can find the first ans 20th term of the A.P
a = (-4(1) + 15) = 11
And,
a_{20} = (-4(20) + 15) = -65
Now, for find the sum of 20 terms of this A.P we have the first and last term.
So, using the formula
S_n = n/2(a + l)
S_{20} = 20/2(11 + (-65))
          = 10(-54)

= -540
Therefore, the sum of first 20 terms of this A.P. is -540.

33. In an A.P. the sum of first ten terms is -150 and the sum of its next 10 term is -550. Find the A.P.
Solution:

Let's take a to be the first term and d to be the common difference.
And we know that, sum of first n terms
$S_n = n/2(2a + (n − 1)d)$
Given that sum of the first 10 terms of an A.P. is -150.
$S_{10} = -150$
And the sum of next 10 terms is -550.
So, the sum of first 20 terms = Sum of first 10 terms + sum of next 10 terms
$S_{20} = -150 + -550 = -700$
Now, having
$S_{10} = 10/2(2a + (10 − 1)d)$
$\implies -150 = 5(2a + 9d)$
$\implies -30 = 2a + 9d$
$\implies 2a + 9d = -30 \ldots . (1)$
And,
$S_{20} = 20/2(2a + (20 − 1)d)$
$\implies -700 = 10(2a + 19d)$
$\implies -70 = 2a + 19d \ldots. (2)$
Now, subtracting (1) from (2), we get
$\implies 19d - 9d = -70 – (-30)$
$\implies 10d = -40$
$\implies d = -4$
Using d in (1), we have
$2a + 9(-4) = -30$
$2a = -30 + 36$
$a = 6/2 = 3$
Hence, we have a = 3 and d = -4
So, the A.P is 3, -1, -5, -9, -13,…..

34. Sum of the first 14 terms of an A.P. is 1505 and its first term is 10. Find its 25th term.
Solution

Given,
First term of the A.P is 1505 and
$S_{14} = 1505$
We know that, the sum of first n terms is
$S_n = n/2(2a + (n − 1)d)$
So,
$S_{14} = 14/2(2(10) + (14 − 1)d) = 1505$
$7(20 + 13d) = 1505$

20 + 13d = 215
13d = 215 – 20
d = 195/13
d = 15

Thus, the 25th term is given by
a_{25} = 10 + (25 -1)15
         = 10 + (24)15
         = 10 + 360
         = 370
Therefore, the 25th term of the A.P is 370

35. In an A.P. , the first term is 2, the last term is 29 and the sum of the terms is 155. Find the common difference of the A.P.
Solution:

Given,
The first term of the A.P. (a) = 2
The last term of the A.P. (l) = 29
And, sum of all the terms (S_n) = 155
Let the common difference of the A.P. be d.
So, find the number of terms by sum of terms formula
         S_n = n/2 (a + l)
         155 = n/2(2 + 29)
         155(2) = n(31)
         31n = 310
         n = 10
Using n for the last term, we have
         l = a + (n - 1)d
         29 = 2 + (10 - 1)d
         29 = 2 + (9)d
         29 - 2 = 9d
         9d = 27
         d = 3
Hence, the common difference of the A.P. is d = 3

36. The first and the last term of an A.P are 17 and 350 respectively. If the common difference is 9, how many terms are there and what is their sum?
Solution:

Given,
In an A.P first term (a) = 17 and the last term (l) = 350
And, the common difference (d) = 9
We know that,
a_n = a + (n - 1)d
so,

$a_n = l = 17 + (n - 1)9 = 350$
$17 + 9n - 9 = 350$
$9n = 350 - 8$
$n = 342/9$
$n = 38$

So, the sum of all the term of the A.P is given by
$S_n \quad = n/2 \; (a + l)$
$\qquad = 38/2(17 + 350)$
$\qquad = 19(367)$
$\qquad = 6973$
 Therefore, the sum of terms of the A.P is 6973.

37. Find the number of terms of the A.P. –12, –9, –6, . . . , 21. If 1 is added to each term of this A.P., then find the sum of all terms of the A.P. thus obtained.
Solution:

Given,
First term, $a = -12$
Common difference, $d = a_2 - a_1 = -9 - (-12)$
$d = -9 + 12 = 3$
And, we know that n^{th} term $= a_n = a + (n - 1)d$
$\Longrightarrow 21 = -12 + (n - 1)3$
$\Longrightarrow 21 = -12 + 3n - 3$
$\Longrightarrow 21 = 3n - 15$
$\Longrightarrow 36 = 3n$
$\Longrightarrow \; n = 12$
Thus, the number of terms is 12.
Now, if 1 is added to each of the 12 terms, the sum will increase by 12.
Hence, the sum of all the terms of the A.P. so obtained is
$\Longrightarrow S_{12} + 12 \quad = 12/2[a + l] + 12$
$\qquad\qquad\qquad = 6[-12 + 21] + 12$
$\qquad\qquad\qquad = 6 \times 9 + 12$
$\qquad\qquad\qquad = 66$
Therefore, the sum after adding 1 to each of the terms in the A.P is 66.
