Mathematics
Exam Important Questions
1. In the given figure, AT is a tangent to the circle with centre O such that OT = 4 cm and ∠OTA = 30°. Then, AT is equal to? [2 Marks]

Join OA.
We know that, the tangent at any point of a circle is perpendicular to the radius through the point of contact.

\[\therefore \angle OAT = 90° \text{ [1 Mark]}\]

In \(\triangle OAT\),
\[\cos 30° = \frac{AT}{OT}\]
\[\Rightarrow \frac{\sqrt{3}}{2} = \frac{AT}{4}\]
\[\Rightarrow AT = 2\sqrt{3} \text{ cm} \]
[1 Mark]

[Diagram of a circle with tangent AT, radius OT, and angle OAT = 30°.]
2. At one end A of a diameter AB of a circle of radius 5 cm, tangent XAY is drawn to the circle. Find the length of the chord CD which is parallel to XY and at a distance of 8 cm from A. [3 marks]

First draw a circle of radius 5 cm having centre O. A tangent XY is drawn at point A.

A Chord CD is drawn which is parallel to XY and at a distance of 8 cm from A.

Now, \( \angle OAY = 90^\circ \)
[Tangent at any point of a circle is perpendicular to the radius through the point of contact]

\[ \angle OAY + \angle OED = 180^\circ \] [sum of cointerior angle is 180°]
\[ \Rightarrow \angle OED = 90^\circ \]

Also, \( AE = 8 \text{ cm} \).

Join OC

Now, in right angled \( \triangle OEC \),

\[ OC^2 = OE^2 + EC^2 \text{[by Pythagoras theorem]} \]
\[ \Rightarrow EC^2 = OC^2 - OE^2 \]
\[ = 5^2 - 3^2 \]
\[ = 25 - 9 = 16 \]
\[ \Rightarrow EC = 4 \text{ cm} \]

Hence, length of chord CD = 2 CE = 2 \times 4 = 8 \text{ cm}
[Since perpendicular from centre to the chord bisects the chord]

-- (1 Mark)
3. If tangents PA and PB from a point P to a circle with centre O are inclined to each other at an angle of 80°, then find the value of \( \angle POA \). [ 3 marks ]
Circles

OA and OB are radii of the circle to the tangents PA and PB respectively. The line drawn from the centre of the circle to the tangent is perpendicular to the tangent.

\[ \therefore OA \perp PA \text{ and } OB \perp PB \]

In quadrilateral AOBP,
Sum of all interior angles = 360°
\[ \angle AOB + \angle BOP + \angle OAP + \angle APB = 360° \]

\[ \Rightarrow \angle AOB + 90° + 90° + 80° = 360° \]
\[ \Rightarrow \angle AOB = 100° \]

-- (1 Mark)

Now,
In \( \triangle OPB \) and \( \triangle OPA \),
AP = BP (Tangents from a point are equal)
OA = OB (Radii of the circle)
OP = OP (Common side)

\[ \therefore \triangle OPB \cong \triangle OPA \text{ (by SSS congruence condition)} \]

-- (1 Mark)

Thus, \( \angle POB = \angle POA \)
\[ \angle AOB = \angle POB + \angle POA \]
\[ \Rightarrow 2\angle POA = \angle AOB \]
\[ \Rightarrow \angle POA = 100° / 2 = 50° \]

\[ \angle POA = 100° / 2 = 50° \]

-- (1 Mark)
4. Prove that the perpendicular at the point of contact to the tangent to a circle passes through the centre.

Let AB be the tangent to the circle at point P with centre O. We have to prove that PQ passes through the point O.

Suppose that PQ doesn't pass through point O. Join OP. Through O, draw a straight line CD parallel to the tangent AB. PQ intersect CD at R and also intersect AB at P.

As, CD || AB, PQ is the line of intersection, \( \angle ORP = \angle RPA \) (Alternate interior angles) [1 Mark]

but also, \( \angle RPA = 90^\circ \) \( (PQ \perp AB) \)
\( \Rightarrow \angle ORP = 90^\circ \)
\( \angle ROP + \angle OPA = 180^\circ \) (Co-interior angles)
\( \Rightarrow \angle ROP + 90^\circ = 180^\circ \)
\( \Rightarrow \angle ROP = 90^\circ \) [1 Mark]

Thus, the \( \triangle ORP \) has 2 right angles i.e., \( \angle ORP \) and \( \angle ROP \) which is not possible.

Hence, our supposition is wrong.

\( \therefore \) PQ passes through the point O. [1 Mark]
5. In the given figure, if TP and TQ are the two tangents to a circle with centre O so that \( \angle POQ = 110^\circ \), \( \angle PTQ \) is equal to

\[ \text{[3 Marks]} \]

\[ \text{OP and OQ are radii of the circle to the tangents TP and TQ respectively. Since, the line drawn from the centre of the circle to the tangent is perpendicular to the tangent.} \]

\[ \therefore \text{OP} \perp \text{TP and OQ} \perp \text{TQ.} \]

\[ \angle OPT = \angle OQT = 90^\circ \]

In quadrilateral POQT,

\[ \text{Sum of all interior angles} = 360^\circ \]

\[ \angle PTQ + \angle OPT + \angle POQ + \angle OQT = 360^\circ \]

\[ \Rightarrow \angle PTQ + 90^\circ + 110^\circ + 90^\circ = 360^\circ \]

\[ \Rightarrow \angle PTQ = 70^\circ \]

\[ \angle PTQ \text{ is equal to } 70^\circ \text{ [1 Mark]} \]
6. In the given figure, QR is a common tangent to the given circles, touching externally at the point T. The tangent at T meets QR at P. If PT = 3.8 cm then the length of QR is

\[ \text{Lengths of the tangents drawn from an external point to a circle are equal.} \]
\[ \therefore QP = PT = 3.8 \text{ cm} \quad \text{(i)} \quad \text{(0.5 marks)} \]
\[ PR = PT = 3.8 \text{ cm} \quad \text{(ii)} \quad \text{(0.5 marks)} \]
From equations (i) and (ii):
\[ QP = PR = 3.8 \text{ cm} \]
But, QR = QP + PR
\[ \therefore QR = 3.8 + 3.8 \]
\[ QR = 7.6 \text{ cm} \quad \text{(1 mark)} \]
7. In the given figure, O is the center of each one of two concentric circles of radii 4 cm and 6 cm respectively. PA and PB are tangents to outer and inner circle respectively. If PA = 10 cm, find the length of PB (up to two places of decimal).

[2 marks]

Join AO, BO, PO

Given that AO = 6 cm, PA = 10 cm, OB = 4 cm

Applying Pythagoras theorem to \( \triangle OAP \)

\[ PO^2 = AO^2 + PA^2 \]

\[ PO^2 = 36 + 100 \]

\[ PO^2 = 136 \] (1 mark)

Applying Pythagoras theorem to \( \triangle OBP \)

\[ PB^2 = PO^2 - BO^2 \]

\[ PB^2 = 136 - 4^2 \]

\[ PB^2 = 120 \]

PB = 10.95 (1 mark)
8. Write ‘True’ or ‘False’ and justify your answer in each of the following:
(i) The length of tangents from an external point P on a circle is always greater than the radius of the circle.
(ii) The length of tangents from an external point P on a circle with centre O is always less than OP.

(2 marks)

(i) False
Because the length of tangents from an external point P on a circle may or may not be greater than the radius of the circle.

(1 mark)

(ii) True

PT is a tangents drawn from external point P. Join OT
\[ OT \perp PT \]
So, OPT is a right angled triangle formed
In right angled triangle, hypotenuse is always greater than any of the two sides of the triangle.
\[ OP > PT \]
Or PT < OP

(1 mark)
9. In the given figure, PA and PB are tangents from an external point P to a circle with centre O. LN touches the circle at M. Prove that PL + ML = PN + MN. [2 Marks]

\[ PA = PB \]  \[ \text{[the tangents drawn from an external point to a circle are equal]} \]  \[ \text{---(1)} \]  \[ (1 \text{ mark}) \]

\[ PL + AL = PN + BN \]

\[ AL = ML \text{ & } BN = MN \]  \[ \text{[same as (1)]} \]  \[ (0.5 \text{ mark}) \]

From above steps,
Thus, \[ PL + ML = PN + MN \]  \[ (0.5 \text{ mark}) \]
Hence, proved.
10. From a point P, two tangents PA and PB are drawn to a circle with centre O. If OP = diameter of the circle, show that \( \triangle APB \) is equilateral. [3 Marks]

\( \angle OAP = 90^\circ \) (PA and PB are the tangents to the circle.)

In \( \triangle OPA \),
\[
\sin \angle OPA = \frac{OA}{OP} = \frac{r}{2r} \quad [\text{OP is the diameter = 2*radius}]
\]

\[
\sin \angle OPA = \frac{1}{2} = \sin 30^\circ
\]

\( \Rightarrow \angle OPA = 30^\circ \)

[1 Mark]

Similarly, \( \angle OPB = 30^\circ \).
\[
\angle APB = \angle OPA + \angle OPB = 30^\circ + 30^\circ = 60^\circ
\]

[0.5 Marks]

In \( \triangle PAB \),
PA = PB \hspace{1em} (tangents from an external point to the circle)
\( \Rightarrow \angle PAB = \angle PBA \) ............(1) (angles opp. to equal sides are equal)

[0.5 Marks]

\( \Rightarrow \angle PAB + \angle PBA + \angle APB = 180^\circ \) \hspace{1em} [Angle sum property]
\( \Rightarrow \angle PAB + \angle PAB = 180^\circ - 60^\circ = 120^\circ \) [Using (1)]
\( \Rightarrow 2\angle PAB = 120^\circ \)
\( \Rightarrow \angle PAB = 60^\circ \) ............(2)

[0.5 Marks]

From (1) and (2)
\( \angle PAB = \angle PBA = \angle APB = 60^\circ \) (all angles are equal in an equilateral triangle)

[0.5 Marks]

\( \triangle PAB \) is an equilateral triangle.
